

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

PATHFINDER FORCING ITS WAY SOUTHWARD

ROADS that are such only in name will be the pathway of the Oldsmobile, that is persistently forcing its way southward, from now to the finish of its journey to the wind-swept Florida beach that connects fair Ormond with picturesque Daytona. Telegraph facilities in northwestern North Carolina may not be of the very best, but, barring mishaps, the Oldsmobile Pathfinder crossed Virginia-North Carolina line on New Year's Day. The last station was from a little railroad junction a few miles north of the border, not far from Danville, Va., one of the largest

towns in the Old Dominion, outside of Richmond. The message was confined to the five words: "Out all night. Heavy rain."

Contrary to precedent, however, the road for the greater part of the first end of the trip has been found to be uncommonly good for this season of the year. On the stretch from New York to Hagerstown, Md., but a few miles of poor road were encountered, though the going was more or less rough in places, owing to the freezing weather, as well as slippery occasionally from snow. This enabled a good pace to be maintained, an

PAYING THE PATHFINDER'S TOLL AT THE HARRISBURG BRIDGE OVER THE SUSQUEHANNA RIVER.

average of 110 miles a day having been made on this portion of the trip. The rolling character of the country, which is almost mountainous in parts, is one of the factors keeping down speed.

Progress Down the Valley of the Shenandoah.

The car left New York Sunday, December 23, the route lying through Philadelphia, Reading and Harrisburg, then by way of the battlefields of Gettysburg and Antietam, and down through the picturesque scenery of the Shenandoah Valley. The roads in the latter are good, and, although it is necessary to ford some of the streams, it is thought that this will become a favorite stamping ground for tourists, as soon as the necessary maps and information are published. Harrisonburg, Va., was reached on the 27th, after four days of steady driving, the trip of 109 miles from Hagerstown, Md., having been made through a severe storm of rain and hail. The total mileage to this point is 410, the tires still holding the air that was pumped into them at New York.

About forty miles outside of Hagerstown, a 25-foot creek had to be forded, and although the water reached within a few inches of the floor of the tonneau, the car went through without any trouble. The roads were so slippery that chains had to be used for sixty miles continuously.

Roanoke, Va., was reached Friday evening, after covering 120 miles of the worst roads encountered up to that time. Mountainous country, through which the roads were of heavy clay, made the going more or less difficult, though the scenery was the finest the party thus far had been treated to. Many points of interest were passed on the day's run, including the famous Natural Bridge. Upon leaving Roanoke, where a number of hours were lost owing to spring trouble, the party got its first taste of the battle that will have to be waged during the remainder of the journey. The roads were so muddy that it was difficult to average more than eight miles an hour, only 35 miles, most of which was done after dark, having been covered.

Struggling Through a Sea of Virginia Mud.

Saturday night found the party at Chatham, Va., which place was left behind early Sunday morning, and after struggling twelve miles through a sea of mud, Bedford Springs was reached, where the gasoline supply was replenished. From the latter point the same kind of going was encountered to Leesville, where it was found necessary to make repairs on an old barge before the car could be trusted to it, in order to ferry it across the Staunton river. On leaving the barge, the car mired on the river bank, and as it was already dark and raining heavily, the night was spent in it. In one place it was necessary to run for half a mile up the bed of a stream two feet deep, in order to reach the road again. Owing to the difficulties encountered, the mileage for two days and one night was only fifty-eight, bringing the total since leaving New York up to 612 miles.

R. H. Johnston, in a White steamer, was met near Harrisonburg, Va., which gave rise to the report that he also was making the trip to Florida. This was not the case, however, as Mr. Johnston was merely on a holiday trip, again starting northward after having met Mr. Owen and his party at the ford in the Shenandoah Valley stream, shown on opposite page.

THE "YANKS" "CAPTURE" A CONFEDERATE CANNON ON THE BATTLEFIELD OF GETTYSBURG.

MORE ABOUT FLORIDA TRIP.

By A. L. WESTGARD.

The article which appeared in THE AUTOMOBILE, November 15, and which gave a preliminary survey of an automobile route to Florida, has attracted considerable attention in the South. One native of Tennessee points out that the roads in the eastern part of his State are "certainly very bad" during a large portion of the year; and, besides, the lack of bridges would necessitate the fording of many streams, a task impossible except in dry weather. Yet it is reported that a party has set out from Minneapolis and intends to traverse eastern Tennessee.

It is also reported that a Boston man "has formulated a plan to establish a highway between the Hub and Atlanta, following the coast the greater part of the way south." While "following the coast" seems a little far-fetched, it has developed upon investigation among autoists who have been in the Carolinas and Georgia that a couple of feasible routes might be mapped out through the red sand country of these States, thus avoiding the route laid through eastern Tennessee.

One route could follow for the major part the one laid out to the Jamestown Exposition at Norfolk and which is being urged for next year's A. A. A. tour for the Glidden trophy. It would follow the Exposition Route's itinerary from New York through Philadelphia, Reading, Harrisburg, Gettysburg, Pa., Hagerstown, Md., and down the Shenandoah Valley to Staunton, Va., up to which point will be found pikes in fair conditions, with innumerable toll gates. Thence leaving the valley, it would cut across easterly over clayey, but on the whole not bad, roads to Richmond, or, if the weather was dry, take the much shorter way south from Philadelphia through Baltimore, Washington and Fredericksburg to Richmond. This route, covering roads not nearly as good as the longer one above, passes through a flat, uninteresting country. Continuing south from Richmond, it would pass through Peters-

WHERE JOHN BROWN WAS TRIED AT HARPER'S FERRY.

burg—at which place it leaves the Exposition Route—Emporia, Va., Halifax, Wilson, Smithfield, Fayetteville and Pembroke, N. C., to Florence, S. C., thence through Sumter, Orangeburg and Bamberg, S. C., to Savannah, Ga., a distance of about 1,030 miles from New York.

Another route could follow the Shenandoah Valley to Staunton and south to Lexington, Va., thence through Roanoke and Martinsville, Va., Winston-Salem, Mocksville and Charlotte, N. C., Chester, Winsboro and Columbia, S. C., Augusta and Waynesboro, Ga., to Savannah, a distance of about 1,040 miles from New York. The territory from Augusta to Savannah is apt to prove itself full of difficulties. From Savannah to Jacksonville, Fla., about 140 miles, there are several stretches of fine

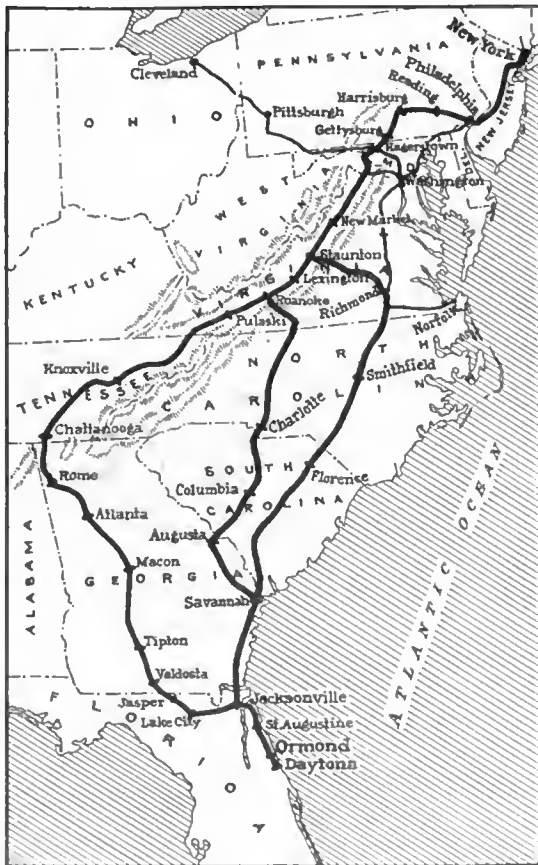

FOUR FEET DEEP FORD IN THE SHENANDOAH VALLEY NEAR HARRISONBURG, VA., WHERE THE OLDSMOBILE AND WHITE STEAMER EXCHANGED GREETINGS.

shell roads and the going ought to be comfortable. As pointed out in the former article, above mentioned, the road from Jacksonville south to Ormond and Daytona, via Pablo Beach and St. Augustine, though sandy and bad in places, has often been covered by automobiles.

The roads through the red sand districts of the Carolinas and Georgia are uniformly good in all kinds of weather, but both routes above given traverse great swampy areas where many detours will undoubtedly become necessary. It is well also to point out that hotels are far between and for long stretches entirely absent, a fact that to a great extent is offset by the generous hospitality of the natives. If one appreciates scenery and does not mind the hardships attendant upon the lack of hotel accommodations, one will certainly enjoy the run through the historic Virginia valley.

The Florida people have become thoroughly aroused to the importance of good roads, and it is intended to employ convict labor to build them, such means being already used in Dade county. The natives realize that since the ascendancy of the automobile, in order to bring a large number of people of means to the State to enjoy its climate—and incidentally to spend their money—they must make it attractive as viewed from the standpoint of an automobile tourist. To no other State in the Union do good roads mean so much as to Florida.

A good beginning has been made, as shown by the excellent clay and marl road just completed from Daytona through DeLand, Sanford and Orlando to Kissimmee, a distance of 75 miles. A new road is also reported as being built from Orlando to Ocala, 65 miles. No doubt that the good work just started will continue and that in, let us hope, the reasonably near future, one will be able to enjoy many extended trips from the winter resorts of the charming State. It is up to the natives to provide the surface; the Northern tourist will do the rest.

THREE ROUTES THAT LEAD TO FLORIDA.

The Oldsmobile Pathfinder that is now en route, is taking the central route from Roanoke to Savannah.

A CORNER IN THE AERO CLUB EXHIBIT AT THE RECENT GRAND CENTRAL PALACE SHOW.

ST. LOUIS SELECTED AS STARTING PLACE.

St. Louis, Mo., January 1.—As the result of a trial ascension made from here to-day in the balloon *L'Orient*, which, after an uneventful trip of several hours, safely landed at Cliffdale, Ill., the special committee consisting of Courtland F. Bishop, Augustus Post, Alan R. Hawley, J. C. McCoy, Frank S. Lahm and Leo Stevens, who came here especially for the purpose of ascertaining if the gas supply were satisfactory for a large event, were unanimous in their selection of St. Louis as the starting point of next year's big balloon race, which is to be held in October.

The balloon was inflated at the yards of the Laclede Gas Light Company, at Second and Rutger streets, and a large crowd gathered to witness the ascension. When the guy ropes were released, the 35,000 foot gas bag rose gracefully in the air until it reached an altitude of about 1,000 feet, when it started to drift slowly toward the west. Alan R. Hawley and J. C. McCoy made the ascension, though they offered to step down in favor of David R. Francis and L. D. Dozier, president of the St. Louis Aero Club, who appeared just as the preparations were completed. The latter, however, declined the honor. When the aeronauts had not been heard from at 10 p.m. telegrams were sent to a number of surrounding towns, but nothing had been seen of the balloon. A wire was later received from Cliffdale, Ill., telling of the safe arrival at that point. The highest altitude reached was 2,100 feet, the earth being invisible most of the time owing to the clouds.

So pleased was the committee with the conditions that it was decided not to visit other cities. The Common Council has set aside a plot of ground adjoining the gas works for the use of the aeronauts. The choice of St. Louis is particularly appropriate, as it was from that city that the start was made nearly half a century ago, resulting in the world's long-distance record that stood until beaten by Count de la Vaux six years ago.

FIRST CONTEST FOR LAHM CUP.

In order to foster interest in aeronautical matters, as well as to commemorate the victory of Lieut. Frank P. Lahm, U. S. N., over foreign aeronauts in the race for the International Cup, the Aero Club of America has decided to offer a trophy for aeronautic races in the United States, the first of which is to be held in connection with the Jamestown Exposition next year. The conditions provide that the first winner of the cup must exceed Lieut. Lahm's record of 402 miles, and each succeeding winner must succeed the record of the previous holder in order to gain it. The Exposition was selected for the first contest, as the Aero Club intends to hold an aeronautic congress in connection with it, at which many of the machines shown will be tested by the government.

IN THE PINES OF NEW JERSEY.

LAKESWOOD, N. J., Jan. 1.—Only 72 miles separates the metropolitan autoist from the heart of the Jersey pine country where automobiling at this time of year is a most pleasurable and exhilarating pastime. In order to appreciate the climatic difference to be obtained by the comfortable run of several hours from New York City one should leave Manhattan Borough in disagreeable weather and note the gradual change as he progresses towards Lakewood. It is only eight miles from New York City to Newark, and thence the route—fully described in "THE AUTOMOBILE Official A. A. A. Blue Book"—is through Elizabeth, Rahway, Metuchen, New Brunswick, Old Bridge, Bloomfield, Spotswood, Helmetta, Jamesburg, Englishtown, passing the Monmouth battleground, thence to Freehold with its military academy, next through Turkey, Ardena, Farmingdale, Lower

A MAXWELL PARTY IN THE PINES NEAR LAKEWOOD.

Squankum, and in a direct line to Lakewood. The road is generally good and sometimes really excellent. Lakewood being the most fashionable of the Northern winter resorts, possesses several magnificent hotels and also Georgian Court, the palatial residence of George Gould, who has constructed a country place costing several millions. John Rockefeller is another frequent Lakewood resident and his golf proclivities make him a familiar figure. The name of Mr. Rockefeller was last week added to the list of notable men who have taken out automobile licenses in the State of New Jersey.

One can return from Lakewood by going to Point Pleasant over one of the best eight-mile stretches of road in New Jersey, thence taking the Ocean Road as far as Seabright, and thence traversing the famous Rumsen Road to Redbank, and go through Middletown, Keyport, Mattewan and Frenault, reaching Old Bridge, whence the down route would be duplicated.

Though there has been considerable criticism of the present New Jersey automobile law, it is anticipated that the coming

CROSSING THE BRIDGE OVER GEORGIAN COURT.

Legislature will make some needy changes that will disarm much of the criticism met with since the Frelinghuysen measure went into effect. New Jersey has the roads and New Jersey intends to build more of the same kind, and if necessary use a different form of construction for the use of the automobile, which even country folk are beginning to realize has come to stay and will be a blessing and convenience to mankind in general.

ALCOHOL TEST PROVED AN EVENTFUL TRIP.

PHILADELPHIA, Jan. 1.—Owing to a delay occasioned almost at the very outset of the trip, by breaking the front axle and a spring through a loose plank wedging in the running gear midway between Jersey City and Newark, Joe Tracy and the Dragon did not reach Philadelphia on the alcohol test run until late last night. The accident occurred at 1:15 A.M., and was due to the fog and rain. A loose section of the plank road sent the car flying into the air, and had Tracy not been proceeding cautiously the mishap might have been serious. Repairs were not effected until Rahway was reached, the road having been lost twice in the meantime. Thirteen gallons of denatured alcohol were consumed on the run of more than 100 miles. Under the old law this would have cost \$35.10, or less the tax \$7.15. About six gallons of gasoline would have been required for the run at a cost of \$1.20.

FAST AUTOS FOR FLORIDA MEET.

H. N. Harding has been selected to drive the new 110-horsepower Oldsmobile in the coming Ormond-Daytona meet. Since the death of Ernest Keeler, at Point Breeze track, Philadelphia, the Oldsmobile people have been looking for a good driver, and Harding's selection probably means he will do all their driving in 1907. Walter Christie is working on a new racer for the Florida meet and hopes to have same in readiness for that event. Two Wayne machines, a 35-horsepower and a 50-horsepower, have been entered by A. L. Kull, New York agent. Arthur Duray, the noted French driver, will compete with his 130-180-horsepower De Dietrich.

THE LAKE IS A SCENE OF GREAT ACTIVITY IN WINTER.

FLOOR PLANS OF THE COMING GARDEN SHOW

SUPPLEMENTING the alphabetical list of exhibitors and the numbers of the spaces that they will occupy when holding forth at the Seventh National Automobile Show, which will occupy the Garden during the week of the 12-19 of the present month, which was published in *THE AUTOMOBILE* last week, diagrams of the various floors showing the exact locations of the various spaces as well as the grouping of the exhibits into classes are shown.

Time-honored arrangements that have prevailed in the past hold good and the imported cars will, as usual, be centered in the restaurant at the right of the main entrance. Commercial vehicles will occupy the basement and sundries and accessories will be found along the balconies and galleries, except that the visitor will have to mount further heavenward this year than ever before, in order to arrive at the level of the first accessory exhibits, for, as announced some time ago, the pressing demand for space in which to exhibit cars has been met in a measure by building an extended platform over the tier of boxes.

"PROSPERITY."

A Garden Show Statue.

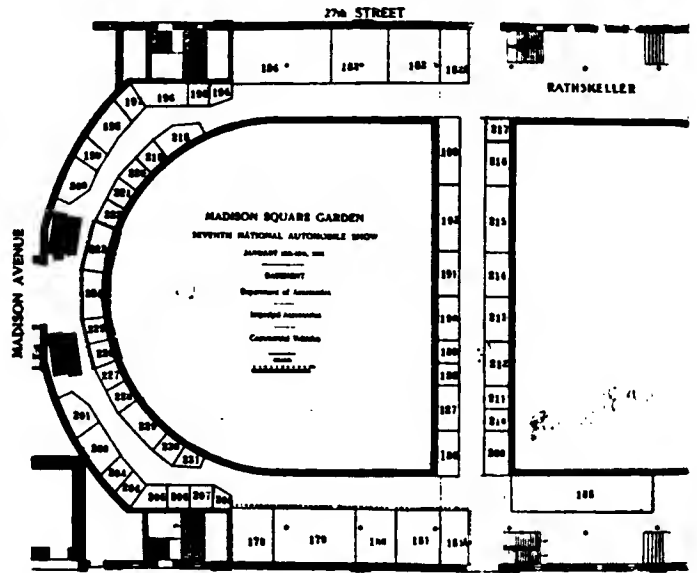

This will be devoted entirely to showing cars, which will naturally be of the lighter weight touring car and runabout types.

What the Show Will Reveal.

Although a number of the 1907 models were not only completed some time ago, but have been sold to purchasers and are running on the roads, it is a matter of common knowledge that a majority of the makers have something or other "up their sleeves" which will not be uncovered until the cars are staged at the show. And though it is well understood that little of radical design is to be looked for, there has been more or less secretiveness regarding just what form the novelties will appear in. Many new things in the shape of detailed changes and improvements in many parts of the car are promised, and while the latter must of necessity be confined to things that make no perceptible difference in the machine in the great majority of instances, those who go looking for novelty will be able to find plenty of it.

There is little doubt but that the combination gasoline-electric chassis of the Electric Vehicle Company will prove the drawing

card of the show, while under the head of attractions, the official press agent mentions a "waterless" fire engine—in other words, a motor fire engine with an air-cooled motor. No new adherents to the six-cylinder principle have made themselves known since last year, so that there will be the same number of multi-cylindere cars of this type in evidence as previously, except that there will be shown a six-cylinder car that has but three cylinders—a two-cycle motor, which is put forth as a substitute for six cylinders of the four-cycle type. The makers of the Pope-Toledo represent one of the few instances in which standards of design have been totally abandoned, their motor having undergone a complete process of revolutionizing during the past year. In accordance

WHERE THE COMMERCIAL VEHICLES WILL BE SHOWN.

with the latest practice it will have both valves in the head, and though the opposite disposition has been retained, but a single camshaft is employed, working through a walking beam type of valve-operating gear. Motor design, where valve placing and operation are concerned, is something that has come in for considerable attention and it is anticipated that its influence will be in evidence on other motors.

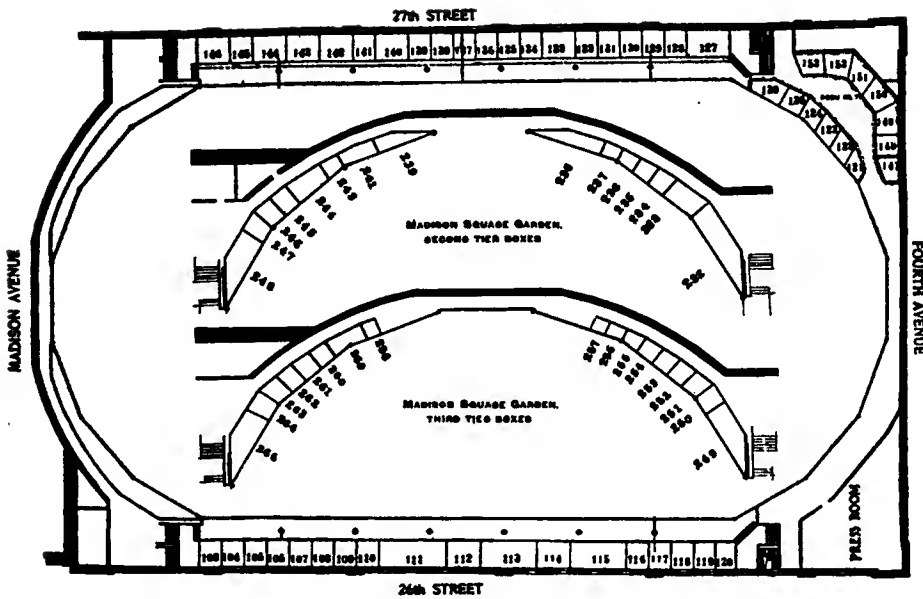

The question of offsetting the cylinders on the crankcase in order to reduce the pressure and consequent friction on the power stroke of the motor is another matter that has received no little attention. The Winton motor represents one of the most prominent adherents to this standard and doubtless others may be

HOW THE MAIN FLOOR WILL BE APPORTIONED.

ELEVATED PLATFORM AND MEZZANINE FLOOR

ALLOTMENTS FOR THE GALLERY; ALSO SECOND AND THIRD TIER BOXES.

looked for. As usual, changes and improvements will be confined for the most part to matters of detail and it is said that more or less novelty is to be looked for in carbureters.

SPACE ALL SOLD FOR THE BOSTON SHOW.

BOSTON, Dec. 31.—Though the Boston show is two months and a half away, the old cry has arisen that the space is all gone, and the manager and show committee of the Boston Automobile Dealers' Association are having difficulty in finding places for all the applicants for space. In Mechanics building and Horticultural hall, which are engaged for the show, the committee had available 105,000 square feet of space. This has been allotted, and if many more applications are received the committee will be forced to take another building. Such a building is available in a new garage that is being erected near Mechanics building, and if this is leased the committee will have 30,000 additional feet of space. At the present time the side walls of the corridors in Mechanics building are being sold to accessories manufacturers who could not secure floor space. Manager Chester I. Campbell has not yet

announced the decorative scheme for this year's show, but he promises that it will be more elaborate and complete than ever before. He is to make a trip next week, during which he probably will close the contracts for the decorations. The show promises to be more complete than its predecessors in every department. There will be not only a greater number of cars, but a larger number of exhibitors of accessories, and the power boat department in the basement will include a larger number of boats than it has in previous years. The commercial vehicle department is also to be larger and more comprehensive.

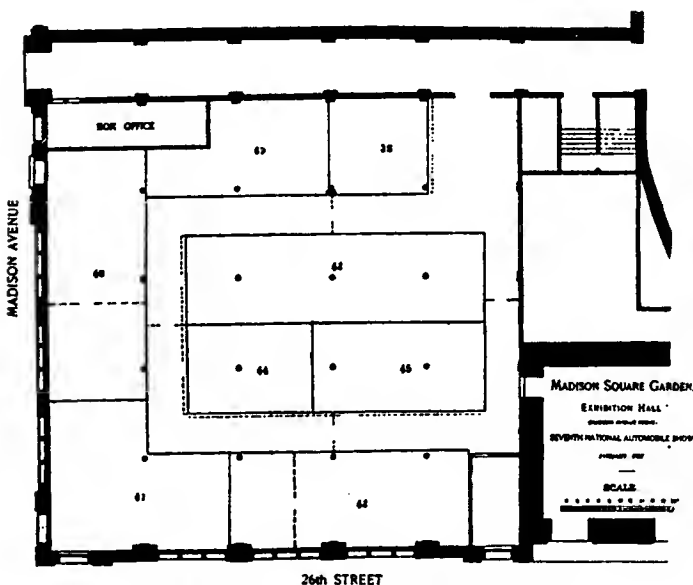

A VETERAN'S VIEWS.

Col. George Pope, who was "among those present" at the beginning of the bicycle manufacturing industry and again when automobiles were first made, says, among other things: "In years gone by, when the old guard makers were new in

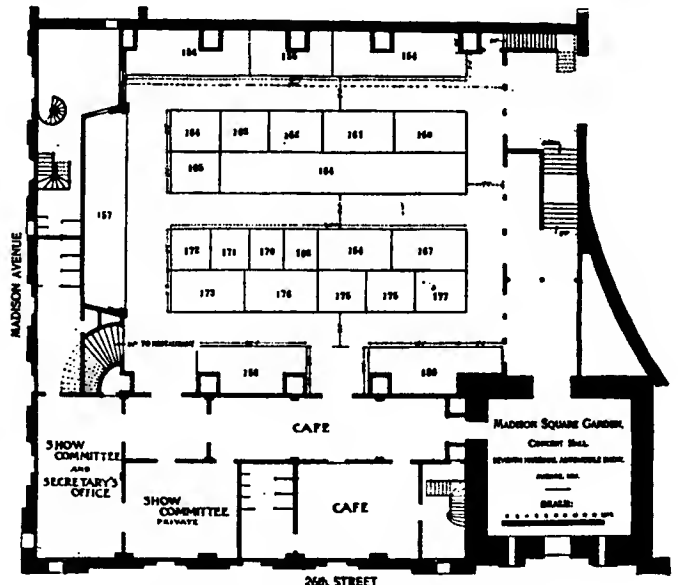

the field and were looking for dealers to handle their product, the national show was largely a trade event, to which the manufacturers went seeking to do business with retailers. Now the old established manufacturers all have their regular line of dealers and the orders from these are booked in the fall. They do not go to the show to engage dealers to handle their output, because they are already supplied in this respect. They go to display the new models to the public, and the show, from being a purely trade event, has become a sort of festival for society and the automobiling class."

PHILADELPHIA'S SHOW OPENS JANUARY 5.

PHILADELPHIA, Jan. 1.—With a score of applicants for space entirely unprovided for, and with the half-hundred or more lucky ones who were able to crowd in inadequately provided for, the annual show of the Philadelphia Automobiling Trade Association opens in the First Regiment Armory next Saturday evening, January 5. Despite this fact, the show promises to be the most successful ever held in the Quaker City.

EXHIBITION HALL SPACES ON MAIN FLOOR.

CONCERT HALL AND ITS APPORTIONMENT.

AUTO CABS IN PARIS.

PARIS, Dec. 20.—It was not until this year that automobiles for the people came into general use in Paris. For a long time there had been a miscellaneous collection of vehicles around the Opera House in which, for as high a price as the driver could obtain, you might have a run around town or make a journey to the seaside—if the motor was capable of it.

FIRST OF THE RENAULT CABS TO REACH NEW YORK.

Paul Lacroix, manager of the Renault Frères Selling Branch, states that arrangements have been practically completed for the formation of an American company which expects to have Renault cabs running in New York City before the end of the year. The cab above pictured is the first one to reach this country, and it has attracted much attention in the Metropolis.

At the end of 1905 a company placed on the streets a number of taximeter cabs, the chassis of which were specially designed and built for town service by Renault Frères. From the first day the venture was a success. No sooner were the 250 Renaults in circulation and doing good business than other firms undertook the construction of machines for this work. At the present moment Bayard-Clément has 200 cabs on order, ten of which are at present on the road. The Darracq factory is building 1,100 chassis for cab work, 800 of which will go to London and 300 remain in Paris. Panhard has a small number in circulation and is building more. Other firms at present building or having finished cabs for Paris are Chenard & Walcker, Georges Richard, maker of the "Unic," Mendelssohn and Tony-Huber. At present the number of cabs in use is about 400, Renaults largely predominating. At the end of 1907 at least 1,500 automobile cabs will be in circulation in Paris.

The rate in Paris is 15 cents for a distance of 984 yards, every additional 328 yards being charged two cents. At night and for journeys outside the city there is a slightly increased tariff. The drivers, many of whom are men previously in charge of horse cabs, are paid a percentage on their takings: 15 per cent. on the part of their earnings below \$6; 20 per cent. on the part of their earnings from \$6 to \$8; 25 per cent. on the part of their earnings from \$8 to \$10; 30 per cent. on the earnings above \$10. Taking \$9 a day as his average receipts, the driver gains \$1.65 a day, to which must be added his tips and a slight percentage earned on gasoline. Each driver buys his own gasoline and is allowed by the company 15 per cent. of his total earnings for this purpose. Generally the driver obtains a slight advantage by this arrangement, the tariff being calculated on average running.

The driver's wages and gasoline paid, an average of 30 fr. 50c. per day and per car remains for the company. Ten centimes (two cents) per kilometer is calculated as the average tire expense, and as each cab runs 130 kilometers a day, 13 francs have to be deducted, leaving 16 fr. 50c. per car. Depreciation is worked

out on a three years' basis, with 300 running days in a year. The price of a cab being 7,500 francs (\$1,500), the amount to be written off is 8 francs per day, bringing the profit down to 8 fr. 50 c. Garage charges, accessories, insurance, etc., take away 3 fr. 50 c., leaving a net profit of 5 francs (\$1) per cab per day.

The Renault chassis supplied to the cab company are in their main lines similar to the firm's standard models, with simplifications rendered necessary by the arduous service they have to undergo. The length of the chassis is 137 inches; wheel-base 100 inches; length for bodywork from dashboard to rear, 96 inches. The track is 51 inches, and the width of chassis 31 inches. Pressed steel frame of the usual channel section, supported on four longitudinal semielliptic springs and one transverse rear spring. The engine, which is carried forward, under the familiar type of Renault bonnet, with dashboard forming radiator, consists of one pair of cylinders 2.95 inches bore and 4.7 inches stroke, rated at 8 horsepower. The most important modification of the ordinary model is the total absence of controlling levers on the steering wheel. There are two foot pedals, the left-hand one operating the clutch and brake on the differential and the right-hand one the accelerator. On the dashboard is a small regulator controlling both the gas and spark, and by means of which exceedingly slow speeds can be obtained. Three forward speeds and reverse of the selective sliding type operated from a single lever, give 5, 9 and 21 1-2 miles an hour. Transmission is of the usual Renault pattern by cardan shaft to rear live axle. Five and three-quarter gallons of gasoline are carried in tanks under the driver's seat, this supply being more than sufficient for a day's work. Gasoline is supplied to the carburetor by gravity feed, and the water circulation is by thermo-syphon. Every effort has been made to produce the simplest possible design, and in this the manufacturers have admirably succeeded. Slight repairs, such as the changing of a tire, ignition troubles, and the like, are attended to by the mechanic himself.

Though elegant in design, the bodywork of the automobile cabs is exceedingly simple. It is constructed by the Company Rhéda, of Levallois, near Paris, and consists of landaulet with folding seat, the rear seat accommodating three and the folding seat two persons. In one minute the top and sides can be folded down, making an open carriage with glass screen between driver and passengers. All the glass windows can be lowered into pockets.

TWO-CYLINDER RENAULT ENGINE OF 8-HORSEPOWER.

FRENCH GRAND PRIX NOT YET SELECTED

PARIS, Dec. 20.—A circuit has not yet been discovered for the Grand Prix of the Automobile Club of France, to be run between June 25 and July 8. Neither of the two circuits in the Fontainebleau has been found suitable for the race owing to narrowness at certain points. A short circuit has been definitely decided upon, but its width must never fall below 22 feet. Several portions of the proposed Fontainebleau circuit only give 20 feet in width without any possibility of widening.

Why One Newspaper Opposes Racing.

The anti-racing campaign has again broken out in a certain section of the French press. *Le Matin*, a daily newspaper of considerable political importance, re-opened the attack yesterday by a violent attack on racing in general and the Grand Prix of the A. C. F. in particular, and terminated by declaring that the Government would not accord the necessary permission for the holding of the race next year. Replies from racing partisans have come forth with promptitude, several journals hinting that *Le Matin's* antipathy to racing only took form when the principal French firm refused to take part in that paper's self-advertising touring contest. A revelation of the personal motives animating the militant non-racers is promised and the squabble may become bitter.

The declaration that the Government will not accord permission for the holding of the race is more of a desire than a reality. No such opinion can have been expressed by any official, for the simple reason that the A. C. F. has not yet given notice of its desire to hold a race. During his visit to the Salon, M. Clemenceau, president of the Council, discussed the question of the Grand Prix with the heads of several important firms, and

showed himself very liberally disposed. In due time the A. C. F. will ask for official permission to hold its race and there is every probability that it will be accorded without serious objection.

Hemery No Longer a Darracq Driver.

Hemery, the 1905 winner of the Vanderbilt Cup, has left the Darracq firm and signed an engagement to drive in speed contests for Tourand & Cie., of Suresnes. Since his last visit to America the dare-devil Darracq driver has not had much success in speed contests, and when a conductor had to be chosen for the 1906 Vanderbilt race, Hemery was sidetracked in favor of his companion, Wagner, who had run up a better speed record during the preceding six months. It is said this setback decided Hemery to quit the firm for which he had won so much glory.

THE RACE FOR THE EMPEROR'S CUP.

BERLIN, Dec. 20.—The Taunus Cup race will take place on June 14, when it is hoped that at least sixty cars will assemble. France and Italy have promised numerous entries, December 31 the lists will be closed. There has been some grumbling about the short period between the issue of regulations and the closing of the entries, but this will give the firms more time to prepare. Up to date of writing Germany is represented by Horch, Opel and Benz, each with a full team of three cars.

Italy is very much in sympathy with the event and has adopted the weight and cylinder capacity limits for the Florio Cup, at the same time stating that the Italian A. C. will not be officially represented in the French Grand Prix. This is quite a feather in Germany's cap.

NOT MUCH DONE AT INTERNATIONAL CLUB CONGRESS

PARIS, Dec. 20.—There was little business of importance at the International Congress of Automobile Clubs, held at the Automobile Club of France this week. Delegates attended from every European country, and America was represented by J. Howard Johnston and William S. Hogan.

In view of the efforts made by the Automobile Club of Switzerland to abolish the numerous petty tyrannies to which autoists have been subjected in that country, it was decided to suspend the boycotting carried on for the past year. In future complaints will be made to the Automobile Club of Switzerland and that body will make inquiries and do everything possible to safeguard the rights of automobile tourists.

Dates Decided Upon for European Events by the International Congress.

Feb. 16.....—Turin Exhibition.
 Feb. 23-26.....—A. C. Italy, Volturette Contest.
 March 20-27....—A. C. Nice, Automobile Week.
 April 2-15.....—Monaco Meeting (Autoboats).
 April 1-15.....—Spring Wheel Competition.
 April 15-30....—Nautical Club of Nice (Auto and Sailing Boats).
 April 18-20....—Targa Florio.
 April 25-28....—A. C. of Touraine, Touring Competition.
 April 28.....—Château-Thierry Hill Climb.
 May 1-15.....—Paris-Madrid Touring Competition and Madrid Automobile Exhibition.
 May 24-27.....—A. C. of Austria, Volturette Contest.
 May 15-31.....—A. C. of Siene and Olse, Wheel Competition.
 May 15-31.....—A. C. of the North, Industrial Vehicle Competition.
 May 31.....—A. C. of Auvergne, Rochet Schneider Cup.
 June 1-4.....—A. C. of Bordeaux, Autoboat Meeting.
 June 8-12.....—Herkomer Cup.
 June 8-12.....—Electric Vehicle Competition (Paris).
 June 14.....—German Emperor's Cup (Taunus Circuit).
 June 15-28.....—Kiel Autoboat Exhibition and Races.

In view of difficulties arising from the diversity of regulations for speed contests—the Grand Prix, the German Emperor's Cup, and the Brescia circuit all being run on totally different lines—the German club proposed a unification of regulations. For 1907 this is impossible, but a new formula will be drawn up and presented at the next congress, to be held on June 15 at Hamburg, on the occasion of the race for the German Emperor's Cup. At the same meeting the question of dates of the different automobile exhibitions will be discussed with a view to obviate clashing of interests. In future the members of the congress will meet twice a year, in December at the A. C. F., and in some other country during the summer.

June 25-July 8.—Grand Prix of A. C. F. (Exact date has yet to be decided upon.)
 July 7-10.....—A. C. of Bordeaux, Touring Competition.
 July 15-18.....—Ostend Week.
 July 19-22.....—A. C. of the North, Baron de Caters' Cup and Leopold Cup.
 July 25-30.....—Belgium Criterium.
 August 2-13....—Auvergne Cup.
 August 14.....—A. C. of Austria (Autoboats).
 August 18-22...—Ardennes Circuit and Coupe de Liedekerke.
 August 23-26...—Ostend Week (Autoboats and Cars).
 Sept. 1.....—Florio Cup on Brescia Circuit.
 Aug. 30-Sept. 3.—Evian Autoboat Meeting.
 Sept. 5-15.....—Arcachon Autoboat Week.
 Sept. 12.....—A. C. of Salon, Speed Contests.
 Sept. 14-15....—Mont Ventoux Hill Climb.
 Sept. 15.....—Semmering Hill Climb.
 Oct. 6.....—Autoboats at Maisons Laffitte.
 Oct. 13.....—Dourdan Kilometer Speed Tests.
 Oct. 20.....—Gaillon Hill Climb.
 Nov. 1-15.....—Volturette Contest near Paris.

REMEDIES FOR ROADSIDE PERPLEXITIES

By THE MAN AT THE WHEEL.

IT is well for the autoist who takes pleasure in grooming his own car, and prides himself on being equal to every emergency, to realize that every case of missed explosions in the motor is not due to either ignition or carbureter trouble. The chances are many to one that one or the other of these is at fault; however, as it has been figured that of the total number of stoppages to which a motor is subject, the ignition is responsible for something like 50 per cent. and the carburetion, in which is included other essentials of the fuel supply than the carbureter itself, 40 per cent. on the average, leaving but 10 per cent. to be accounted for by all other troubles of whatever nature. And one of these other troubles that will produce symptoms so nearly akin to those indicating ignition or carbureter ills as to invariably lead the search in their direction can frequently be traced to a leaking inlet valve. No better illustration of this can be cited than the case of a high-powered car which persistently missed despite every effort to locate trouble in the ignition system or the carbureter. Every test proved them to be working at their best, so the valves were finally removed, and it was found that the inlet valve of cylinder number three had quite a piece chipped out of its edge, causing it to leak badly. This permitted the gas under compression to be forced back through the manifold and out through the main air intake of the carbureter. Consequently cylinder number two, which was next in order to fire, did not receive any charge and missed fire. At times number three would force most of the charge out through the hole in the valve so that it would also miss, causing the latter to apparently jump to different parts of the engine in an extremely puzzling manner.

One of the Causes of Lost Power.

Few things are more puzzling to figure out for the driver whose experience does not date back very far than a motor that will run perfectly at low speeds, but which begins to sputter, misfire and choke the moment an attempt is made to accelerate it. The symptoms are indicative of carbureter trouble, and anyone who recalls his experience with the old time non-compensating carbureters, in which it was necessary to alter the amount of air given for every change of motor speed, does not have to puzzle very long as to the cause. On the other hand, a driver whose experience has been entirely with the present-day automatic carbureters, in which adjustment is practically confined to giving the needle valve a turn one way or the other in order to alter the amount of fuel entering the nozzle, does not find the problem so easy of solution. Traveling along a country road not long ago the writer came across a driver who found himself in this situation. He had been going along smoothly at a good pace, up hill and down dale, when suddenly the motor seemed to go into a tantrum. It sputtered, popped and "laid down." The first twist at the crank set it running again as smoothly as ever, and the driver resumed his seat preparatory to getting under way, feeling much relieved that things were not half as bad as the symptoms seemed to promise. But he was doomed to disappointment, for the moment he tried to speed up the engine and let in the clutch the same performance was repeated, and the engine stalled. He had been going through this process for half an hour or more when we came along, and the impatience of the people he was driving had about reached a point where they were tempted to walk to the nearest railroad station and continue their journey that way. The helpless, exasperated look of the chauffeur would have been enough to melt the heart of the autoist least inclined to render assistance had the passengers not actually signaled us to stop. Of course, they were of the opinion that the case was utterly hopeless and merely wished the favor of a lift to the station, while the chauffeur thought of nothing but a tow. Before we did either an investigation

was undertaken, and the motor having duly displayed its symptoms at the beck of the chauffeur for our benefit, the carbureter was tackled. The trouble was apparent even without dismantling it. A spring controlled plate closed the opening of the auxiliary air inlet, and, under ordinary conditions, its adjustment should have been such as to cause it to yield to the slightest touch of the finger; but, as it was, poking it with a pencil end failed to disturb it. It had jammed tightly on its seat, with the result that when the motor speeded up the mixture became so rich that the engine could not possibly run on it. An unusual bump had unseated the spring and caused it to bind against the side wall of the intake, and as soon as this was set right there was no further trouble with it.

Poor Adjustment Weakens the Motor.

It is one of the peculiarities of the automobile motor that it will very frequently run perfectly, or apparently so, at a low speed, sometimes even carrying the load well on low gear, and all but refusing to perform when a higher speed is attempted or the direct drive is employed. Next to having the engine in perfect running order, while a break in some one of the links of the transmission prevents progress, there are few things more exasperating than being compelled to crawl along at six or eight miles an hour on the low gear with the engine running as if it would shake itself off the car. Such a state of affairs is usually considered to be indicative of about as small an amount of skill in driving as a man can possibly possess and still manage to run a car. In the great majority of cases it can be traced to the coil vibrators and the sluggishness of the latter can, in turn, be laid to the battery in many instances. It is safe to say that in nine cases out of ten the coil vibrators are adjusted so as to take anywhere from one to three times as much current as is actually needed to run the engine up to its maximum. In other words, two-thirds of the current is usually wasted, and still many autoists condemn their batteries because the mileage obtainable from a charge is so small. As soon as the battery falls off a bit there is not sufficient current to start the vibrator working as quickly as it should, and in consequence the coil works sluggishly. It lags, and no matter how far the time of ignition is advanced, the charge is, in reality, not being fired until much later in the stroke, which readily accounts for the loss of power. With a motor turning over at the rate of 1,000 r. p. m., but .03 of a second are required to complete the power stroke in each cylinder so that the time element becomes of extreme importance. It is easy to realize that no matter how small a fraction of a second the vibrator lags behind the moment of contact at the timer, this is bound to exert considerable influence on the time that the explosion occurs in the cylinder. The vibrators should always be adjusted with the engine running, and, if possible, with the aid of a low-reading ammeter; that is, one on which the dial is calibrated into easily readable fractions of an ampere. The fluctuations of current are so violent, however, that an accurate reading will only be possible by holding the vibrator down momentarily. This will give a higher reading than the amount of current actually used, but will be valuable as a comparison.

Some Things Worth Remembering.

A sudden and complete stopping of the motor points a break in the ignition system almost invariably; gradual slowing down and weakening of the motor may be due to either the ignition or failure of the fuel supply, while spasmodic running is most often caused by the former. These and a few other fundamental principles of like nature if constantly borne in mind will frequently be the cause of being able to put your hand right on the trouble.

TIRES, PATENT RIMS, AND WHEELS AT THE SALON

By W. F. BRADLEY.

PARIS, Dec. 20.—The whole interest of the tire section at the Paris Salon centered in dismountable rims. At the beginning of the year three French firms at most were constructing appliances for quick changes of tires; at the Salon there was hardly a stand without some form of quick-change rim, emphasizing a remarkable advance within the year.

VINET RIM SECURED BY MOVABLE WEDGES.

secured to projecting bolts on the face of the rim, for convenience in changing an outer shoe. Formerly it was necessary to take the rims off and struggle with them on the floor or on a table. By the new method changes of tires on spare rims are easily carried out. Ssizz won the Grand Prix largely owing to his M. L. rims, using an American brace for taking off the nuts. With the new model an improved brace is supplied, known as the "revolver," from the fact that it takes up the nuts as they are unscrewed and holds them one behind the other within itself. The nuts have never to be touched with the fingers, so there is no danger of them falling to the ground. The box

METHOD OF SECURING MICHELIN

key has within it a coil spring pushing a metal disc to within a certain distance of the mouth of the key. Around the tube are three long, flexible, steel blades, each with a projecting head passing through a hole into the interior and close to the mouth of the tube. As each successive nut is engaged on the key it passes behind the spring heads, and is thus prevented from falling out, while the coil spring behind keeps it pressed against the heads in position to be engaged again on the bolt. With this tool the six nuts can be taken off and put on again in less than a minute.

VULCAN DISMOUNTABLE RIM.

M. L., and one which also stood its test in this year's European races, was shown without any changes on the model already described in these columns.

Michelin, who brought out a dismountable rim at the time of the Grand Prix, has now an improved model, which he states will be ready for delivery early in February. Instead of metal wedges forced between the fixed and the movable rim, which had a tendency to stretch the latter and finally cause it to burst, the movable rim is secured by eight hooks clasping round its curved surface and held in position on a

bolt projecting from the face of the wooden rim. The fixed rim has a steel surface with a groove, into which a projection on interior face of movable rim keys to prevent creeping of one rim on the other. In the accompanying sketch *A* is the hook, *B* the bolt passing through it, *C* the movable rim, *D* the fixed metal rim; and *E* the wooden rim.

Jenatzy, the famous Mercedes driver, bases his dismountable apparatus on the principle of fixed steel wedges on the exterior surface of the fixed and the interior surface of the movable rim. There are about a dozen pairs of wedges on the two surfaces, and as each pair is brought together the wedging effort is increased. To secure the two rims, a flat steel wedge with a bolt at each end is inserted laterally and driven home with a hammer.

SAMSON PATENT RIM.

The Vulcan Tire Company presents two types of quick-change tires, the one providing for a change of inflated tire and rim, the other a dismountable flange for easy withdrawal

SADJAL RIM WITH EXPANDING BAND.

of inner tube. For the latter operation the outer metal flange is movable, and has on its inner surface a number of projecting flat-headed studs entering into holes prepared for them on the metal face of the wheel. A slight forward movement of the flange drives the studs home in their grooves and a single screw prevents further movement. The type providing for change of inflated tire and rim has steel-faced fixed rim and ordinary movable rim. On the face of former are a number of diagonal grooves running contrary to forward motion of wheel; and on the movable rim are corresponding flat-headed studs.

Samson, the leather tire manufacturer, has a rim similar to the Michelin and the M. L., secured by means of six cams on the outer surface of the fixed rim. When turned into closed position a spring prevents further movement of the cam. A box key placed over the nuts to release the cams presses on the head of the embedded spring, allowing free movement. A complete valve

LE REVE CIRCULAR BAND WITH LOCKING APPLIANCE

is left on the Samson, provision being made for it by a hole in the fixed rim.

The Sadjal rim is of the Vinet type, with projections and grooves on movable and fixed surfaces, and final locking by a broken circle with right and left thread screw for closing up.

LE RÊVE RIM UNLOCKED.

LE RÊVE RIM LOCKED.

Le Rêve is on similar lines with the difference that the broken circle is fixed within grooves and expanded by a strong spring. By pulling down a single lever the expanding band is reduced in circumference, allowing the movable rim to slide off.

The Sider is one of the most original of several attempts made to produce an unpuncturable tire. It has an outer surface of rubber

on the usual canvas basis, behind it several layers of semi-circular steel with interpositions of woven cloth. Half the space usually occupied by the air chamber is empty, the other half is fitted with separate blocks of wood held in position by security bolts, wedging the outer shoes exactly as is done by an inflated air chamber.

Elastès is a composition with a rubber basis which is boiled to a liquid point and molded to the shape and size of an air tube. A protecting band is placed round it and the mass put inside an outer shoe. The composition can be made to any consistency to suit different weights. A powerful company has taken up the patent and has secured the adoption of these solid tires on Paris cabs.

SIDER UNPUNCTURABLE TIRE

The Ducasble is a tire seen at the show last year and presented now in an improved form. It is a rubber tire with a number of small independent air chambers, each one about the size of an egg. As each chamber comes in contact with the ground a certain quantity of air is driven out through a small hole on the side of the tire, fresh air being drawn in as soon as pressure is removed.

THE DUCASBLE RIM.

J. S. Fougerat has an economical tire protector. An old shoe, or one that is showing

signs of wear, has its heels cut off and a large number of hooks riveted along each edge. To prevent the metal coming in contact with the under tire the canvas is opened along its edge and the hooks inserted between two layers. This protecting band is placed over a good tire, the hooks acting just as the original heels did in holding it on the rim by pressure from the air chamber. Other firms have the same kind of hooks fitted on new bands to place over an ordinary pneumatic automobile tire.

A HYDRAULIC SHOCK ABSORBER.

Shock-absorbing or spring-retarding devices, of which there is at present such an apparently diverse assortment on the market, may be divided in reality into three groups, depending on the basic principle of their operation. These are friction, pneumatic and hydraulic devices, and the majority are of either the first or the third class. Probably the most prominent of the

APPLIED TO CAR FRAME.

APPLIED TO CAR AXLE.

last-named order, and which may be said to occupy a position of its own, is the Hotchkiss Anti-Jolt device. It is unique in that it is not designed to absorb the jar and jolt, but to eliminate them. And the latter occur on the up-thrust, when the springs, which have been forcibly compressed, expand rapidly and literally throw the body of the car and its occupants. The Hotchkiss Anti-Jolt device, which acts on the same principle as that applied to modern high-powered guns to take up the recoil, consists of a piston and cylinder, the latter being divided by a partition in which an adjustable valve is placed. The cylinder is filled with glycerine, excluding the air, and the action of the piston forces it through this valve, the device being so placed as to allow the springs their natural flexibility on the down-thrust, the piston starting to retard the upward movement as soon as they have reached the lowest point of their compression. The device may be readily adjusted to adapt itself perfectly to any car from a light runabout up, merely by altering the opening of the by-pass valve mentioned. This is done from the outside by loosening a lock-nut and setting up or unscrewing the valve adjusting screw. The device is also easily applicable to any type of car and is equally efficient in any position. The methods of applying it to either the axle or the car frame are shown by the accompanying line illustrations.

PECULIAR PROPERTIES OF WOOD.

Wood is possessed of several peculiar characteristics where its employment in connection with an electric current is concerned, and a knowledge of them on the part of the autoist will probably serve to make plain some otherwise puzzling conditions. When dry, wood is an excellent insulator, but this quality disappears with its dryness, the current finding a path across the wet surface; when charred or blackened by heat it also becomes a good conductor, but when reduced to ashes it is again a non-conductor.

DEVELOPMENT OF THE TWO-CYCLE ENGINE—PART II*

By C. P. MALCOLM.

THERE is another type of engine that involves much of the same general principles as the independent supply cylinder class that we have just described, and much that we have said of it will apply equally well to this. In this class the lower or pump end of the piston is enlarged. A good proportion is to make its diameter one and one-half times that of the power end; a 4-inch bore cylinder would have a 6-inch bore air pump. As

PROPOSED DOUBLE PISTON TYPE OF TWO-CYCLE.

there is no water jacket or air-cooling fins around the air pump end these cylinders take up no more room than an ordinary gas engine cylinder, but the enlarged end gives it a more symmetrical look, and it does not have a top-heavy appearance. The upper part of the air piston is used as the pump and the air is drawn in and expelled from the space between the cylinder walls of the pump and the trunk of the power piston, and with the sizes we have given it will pump one and one-quarter times the volume that the power piston would. There are three cylinders with their cranks 120 degrees apart, and the up stroke of the cylinder on the end will feed into the inlet port of the cylinder next to it; the latter will in turn feed the cylinder on the farther end and it will feed back into the first cylinder. By this arrangement the inlet port of each cylinder closes a little before the pump feeding it has completed its stroke and the full volume will not be delivered with the dimensions that we have given, but the volume delivered will exceed the piston displacement of the power cylinder.

Independent Supply Cylinder Type Considered.

A better form of construction for this type of engine is made by following the lines pointed out in our study of the independent supply cylinder type, having all of the pumps discharge into one conductor, common to all of the inlet ports. Then each cylinder will take its full charge when its port opens, regardless of which pump is furnishing the supply. In this way there will be no compression above that necessary to make the transfer of the charge from the pump into the cylinders, because some one of the three inlet ports is open more than three-fourths of the time, while in the other way there is considerable more than one-third of the air pump stroke made before the inlet port of the cylinder that it is supplying opens. Considerable of the time two cylinders are pumping at once. By using the single conductor the full one and one-fourth volume of charge will be delivered into the cylinder each time. The engine can be regulated by the throttle and the relief valve method, described in

connection with the independent supply pump system, and this is much the better way to regulate. A simple revolving cylinder valve can be made, extending so as to embrace all three of the cylinders and controlling both the intake and the outlet of all of the pump cylinders accurately. This is cheaper, more positive, and more satisfactory in every way than using check valves. This revolving cylinder valve can be run with a silent chain and sprocket or by gearing, making it revolve in unison with the crankshaft.

While the check valve action is almost a necessity in four-cycle practice, the excessive heat making rotary or sliding valves impracticable, and a piston valve, the only alternative, is not only expensive, but cumbersome, there is generally no excuse for using check valves in two-cycle practice. Simple methods of obtaining the required action with rotary and sliding valves are available and are much better and more satisfactory in practical use, being free from jerk and destructive jar. This engine will give better satisfaction when built with a rotating cylinder valve than any other mechanism of its class, making the same number of explosive impulses as six cylinders of the four-cycle type and its action as flexible and as easily controlled in every way.

Some Conclusions Which May Be Arrived At.

Both this type of engine and the independent supply cylinder type, in the perfected form that we have described, are such a long step in advance of the four-cycle that it can only be a question of getting a few of them before the automobile public, so that they will know that there are such engines to be had, before they will take their proper place in the foremost rank of automotors. There is no question but what a three-cylinder engine of either of these types will develop more power than six four-cycle cylinders of the same size, with not to exceed one-third of the mechanism, and that of a simpler and much more durable kind and only one-half the weight. The value of this light-weight feature will appeal with overwhelming force to those who have been connected in any way with building racing machines and have had to keep the weight down to a certain definite limit with the greatest power possible within that weight.

There are, of course, some who will doubt that a two-cycle engine can be made that will develop twice the power that a good four-cycle motor will, although it does get twice the number of explosive impulses. The laws governing the action of an explosive charge in a gas engine are certain and inexorable, and if certain conditions are complied with, certain results are obtained. If the charge in the cylinder is pure, the most powerful explosion possible will be obtained, assuming the same compression in every case, regardless of the "cycle" of the engine. The explosion will be less powerful in rapidly increasing proportion to the quantity of foul gases there are mixed with the charge. Of course, if the cylinder be not charged to its full

INDEPENDENT PUMP WITH RECEIVING CHAMBER.

*Continued from THE AUTOMOBILE, December 27, pages 915-917.

capacity, some burnt gas will be left in it, as it is full of exploded gas at the end of each stroke.

The ordinary two-cycle motor does not develop twice the power of a four-cycle; that is, its explosive impulses are not as powerful as those of a four-cycle engine, because we do not get into its cylinder as full a charge as we do into a four-cycle cylinder. The amount of charge drawn in varies according to the design of the engine. We consider that the design given in part one of these papers marks the closest approach to good practice in this respect, but it will not deliver into the cylinder quite the full quantity; there will be a few ounces of pressure in the crankcase when the piston begins its up stroke, and this pressure represents the amount of charge that should have gone into the cylinder, but did not.

Forcing the Gas Into a Three-port Motor.

When we take the three-port engine, and probably three-fourths of the two-cycle engines, built to-day are three port, we find that not more than two-thirds of the charge that is supposed to go into the cylinder actually does so. We will suppose that the stroke of a three-port engine is four inches, the inlet port of the cylinder is five-eighths of an inch and the inlet port to the crankcase is also five-eighths of an inch. (They are often nearer an inch.) Of course no compression takes place in the crankcase until the piston has descended the width of the port and covered it, after which what charge there is left in the crankcase is compressed and will go into the cylinder as soon as the inlet port is uncovered by the piston. As soon as the piston begins its up stroke it produces a vacuum in the crankcase, and it will suck back from the cylinder into the crankcase again until the cylinder port is covered by the up stroke of the piston. Thus it will be seen that all of the stroke of the piston, measured by the width of the port admitting the charge into the crankcase, plus the width of the inlet port of the power cylinder, is lost, as far as getting charge into the cylinder is concerned. We only have two and three-fourths inches out of the original four-inch stroke that will be actually useful in putting charge into the cylinder. When we remember that even this is not all delivered into the cylinder, there being other losses incidental to all transfers of elastic gases from one space to another within a given time, we see abundant reasons why the explosive impulses of such an engine should not be as powerful as those of a four-cycle, as well as for the general distrust of two-cycle engines, when that type of two-cycle motors is the best that we know of.

A NEW TIRE FILLING COMPOUND.

Numerous efforts have been made to discover a substance that would possess the property of resiliency in a high degree, without at the same time having the disadvantages of melting at a low temperature, that would not decay or disintegrate and that would not injure the rubber of the tire into which it was injected. Attempts to discover such a material date back to early bicycling days, but none of them proved an unqualified success, and few, if any, have survived to this day. Now L. S. Lewis and C. H. Cooley, of Hartford, Conn., think they have hit upon the secret. Their compound is injected in a molten state and is not affected by ordinary changes of temperature as well as being proof against oil and grease; nor does it harden with age. Several Hartford autoists have tried the new substance in the tires of their cars and vote it a success, as the result of which a company, to be known as the Elastro Manufacturing Company, has been organized with \$50,000 capital to market the compound. H. B. Philbrick is its president. Patents have been applied for.

A Tourist Trophy race for motor cycles has been included in the 1907 program of the British Auto Cycle Club, to take place, if possible, the day after the car event on the Manx course. The costly and weary Land's End-John O'Groats trial has been discontinued and a six days' reliability tour, with start and finish in London, will take its place.

ANTI-SKID AND SMOOTH TIRES.

At this season of the year, when anti-skid tires are so generally used, it is well to remember that all shoes with a rough or steel-studded surface have a shorter life than smooth surface tires. M. Michelin, the tire expert, has given the following explanation of this: Every tire is composed of two distinct parts, the carcass which gives the support and the internal air pressure, and the web, frequently vulcanized on the carcass and which may be round, flat, or anti-skidding. The web is the part of the tire which comes in contact with the ground and has to resist road friction. The carcass only receives the reactions of the road through the web, and it is thus easy to see that the nature of this latter has considerable influence on the life of the tire. If two similar carcasses are taken, and one covered with a smooth web and the other with an anti-skid surface, it is the anti-skid tire which would perish first. An anti-skid band is intended to prevent side movement, and to obtain this result metal rivets are interposed on the surface of the tire, this interposition causing a considerable adherence of the tire with the road, and in consequence an integral absorption of all effort or reaction by the anti-skid band.

To be effective every anti-skid must be harsh, and unfortunately it is only harsh to the detriment of the life of the tire. Whatever may be the nature of the band, a steel-studded surface always causes greater strain on the tire.

A smooth tire, on the contrary, has less adherence with the road, slipping over the ground under the influence of harshly applied brakes or a too sudden start. The carcass in consequence is subject to less strain. By careful driving, especially by judicious use of the brakes, the causes of deterioration of anti-skid tires can be diminished. But if the same careful treatment were given to smooth tires their life would be lengthened in increased ratio. As a set-off against the shorter life of anti-skid tires is the fact that they are rarely punctured by stones, glass or nails.

Drivers in long-distance European touring competitions are unanimous in declaring that good anti-skid tires never puncture. When they are worn thin they burst, but give no previous trouble.

A PUNCTURE-PROOF TIRE FROM AKRON.

AKRON, O., Dec. 31.—L. Greenwald, superintendent of the tire repair department of B. F. Goodrich & Co., has invented a puncture-proof tire which at present is passing out of the experimental stage, as it has proven under exhaustive tests to be more than was anticipated. It is likely that steps will be taken before long to introduce and manufacture the tire. It is claimed for this tire that it answers all of the purposes of a tire that is not puncture-proof, which most so-called puncture-proof tires do not do, and at the same time it is fully punctureless.

The invention involves three constructions of puncture-proof tires, molded in the outer cover, on the inner tube and separately. Owing to the materials employed and the nature of its construction, the resiliency or present features of the tire is not affected in the least. The old cases in which the protector is used in this tire are kept whole on account of the reinforcement and the elimination of blowouts resulting from rupture in the outer case or from an imperfection in the material or construction.

In connection with the protector there is a special construction of tube, and this combination practically eliminates all injury except natural wear.

The nature of the test to which the tire has been subjected successfully indicates its worth. The tire was placed on an auto owned by a physician and a pound of nails and spikes were driven into a plank and the plank fastened to the floor. Then the car was driven over the sharp points, first slowly and then fast, and the tire came out of the test uninjured, it is claimed.

Bosnia is the first country in Europe to issue a postage stamp with the picture of an automobile, the new 50 hellers bearing such an impression.

STEAM FOR PUBLIC SERVICE VEHICLES

STEAM as a motive power for public service vehicles was the subject discussed at the monthly meeting of the British Institute of Mechanical Engineers in a paper read by Thomas Clarkson, member, of Chelmsford, England. He said in part:

"The selection of the motive power for public service vehicles must be considered in its relationship to the public safety and the convenience, as well as with respect to the state of the art. It has been commonly supposed that steam was unsuitable, and assuming the ordinary methods of application, this conclusion is probably correct. The question arises: Is one justified in assuming that ordinary methods represent its highest possibilities? One object of this paper is to show that this is by no means the case, and that recent developments in the methods of harnessing steam for public service have entirely altered the situation.

Some Advantages That Are Claimed for Steam.

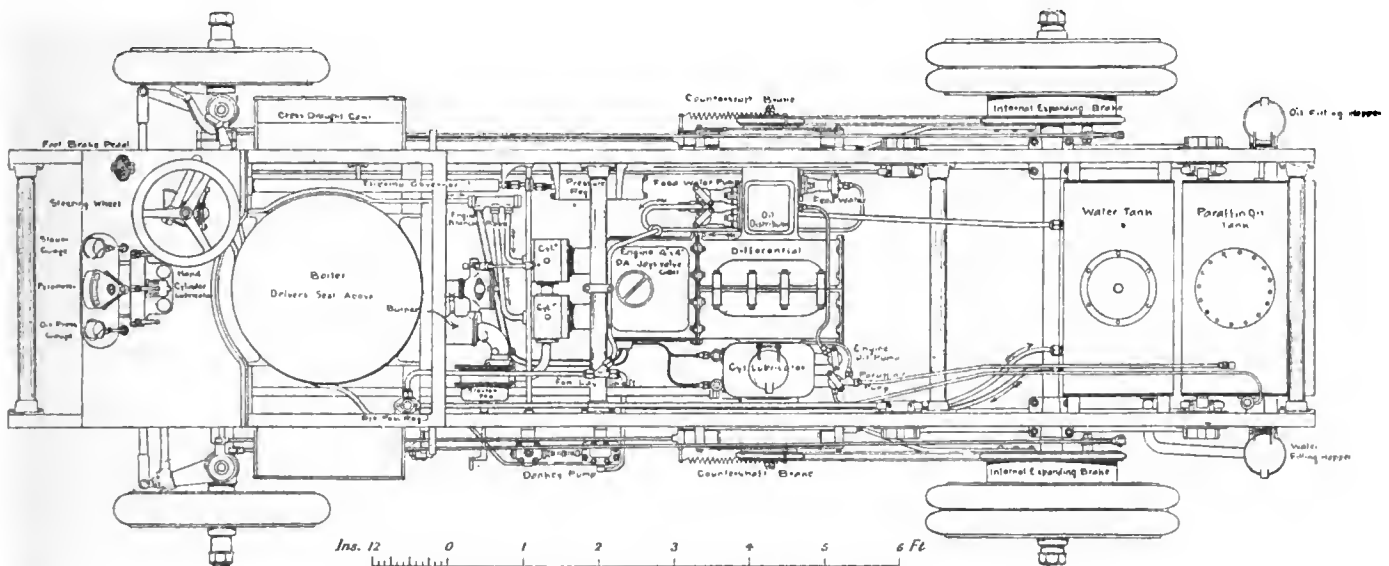

"In 1905 the first double-deck steam omnibus of the author's construction commenced regular service, and at present there are

transformed to a gaseous state. The vapor is mixed with air—on the Bunsen principle—before ignition takes place, and the heat maintains the temperature of the vaporizer.

Concerning the Burner and Oil-supply.

"The main fuel-supply is carried in a tank not subjected to pressure and therefore can be replenished quickly without extinguishing the burner. The kerosene is pumped from the main tank into a pressure tank of solid-drawn steel, which is about half full of air. This forms a cushion which keeps the burner fed when the car is standing and the pump not delivering oil. The surplus oil delivered by the pump escapes through a spring-loaded relief-valve set to about 40 pounds' pressure and returns to the main tank.

"Simple and expeditious starting of the burner has received much attention. Preliminary heating with alcohol is slow, uncertain and expensive. The employment of the two fuels (one for starting and another for running) is also objectionable. The

PLAN VIEW OF CHASSIS CLARKSON STEAM OMNIBUS

about forty licensed in London. The advantages of steam for public service may be generally summarized as follows:

- The employment of a safe and cheap fuel.
- Freedom from noise, vibration and smell.
- Smooth and silent action of the machinery.
- Quick acceleration, flexibility, and ease of control.
- Large reserve power for hills and for starting.
- Entire absence of change-speed gears and friction clutch.

"To realize these important advantages a perfect steam-generator is necessary. Here the principal engineering difficulty has been encountered. The usual methods are characterized by smoke, dirt, constant attention to water-feed and stoking, trouble from priming, incrustation, and leakage. Therefore it is safe to conclude that the usual methods are unsuited for the purpose. To produce a generator free from the above vices has proved a serious problem. It is surprising to many engineers to find that steam can be generated automatically as required, and that the generator has been made, for all practical purposes, foolproof.

"For the purpose of description, the generator may be conveniently divided into three parts, namely, the burner, the boiler, and the governing gear.

"The burner is constructed upon the principle of supplying kerosene under constant pressure to a vaporizer, in which it is

preliminary heating is now done in one minute with kerosene, and the heat obtained as follows: A cast-iron box contains several asbestos wicks saturated with kerosene which readily ignite from a match. A current of air is blown from a fan into one side and through the other side of the box a strong flame is driven. The flame is directed against the body of the burner so as to ignite the mixture as soon as it appears. This arrangement will start the main burner in fifty seconds, and the omnibus can move by its own steam in ten minutes from 'all cold.'

Only Water Tube Boilers Are Used.

"The boiler is constructed wholly of water-tubes. These are disposed so as to absorb the maximum heat from the products of combustion before the latter are allowed to escape, by employing the regenerative principle. The tubes nearest the fire are maintained at a fairly constant temperature by a thermostat and the water-feed is governed directly by the steam pressure.

"The governing gear is a most vital part of the generator combination, since upon it depends the very existence of the boiler itself. It may be divided into fire-control and water-control. It must be understood that the full power of the burner is in excess of the maximum demands for heat, and the flame is continually checked by the governor, regulating the supply of steam in accordance with the variations of the load. The main principle is

the maintenance of an equable temperature in the steam; in other words, the supply of heat to the generator is governed by the temperature of the steam generated. The employment of highly superheated steam is essential for economical working and 700 to 800 F. is found to be a convenient temperature. The automatic water-control of the generator is in the form of a by-pass regulated by the steam pressure. The pumps are always taking the full charge of water, which is either delivered into the generator, or allowed to return to the tank, should the by-pass be open. There is no intermediate condition.

The Engine.

"The engine has two horizontal double-acting cylinders, 4-inch bore by 4-inch stroke, in two separate castings. They are attached to distance-pieces bolted to the outside of the aluminum gearbox, which contains the crankshaft, crossheads, connecting rod, and all the valve motion. It is found convenient to place the valves for the distribution of the steam beneath the cylinders, as this dispenses with the necessity for the employment of

BURNER AND STARTER DETAILS.

draincocks for removing the water of condensation at starting. The valves are of the piston type fitted with rings, and are actuated by Joy gear. This enables a very simple form of crankshaft to be employed, built up of two parts, each forged out of the solid and bolted together with a steel spur-wheel in the center. The cranks are at right angles. No adjustment is provided, but large and well-fitted surfaces of the hardest bronze working against a hardened and ground steel face are provided and with a constant flow of oil over them. Such an engine will run 30,000 miles without developing any appreciable knock.

Some Features of General Arrangement.

"An air-condenser is placed in the front of the chassis, forming the front of the bonnet, and in this is housed the generator. The engine is between the generator and the rear driving-axle. The cylinders lie horizontally and forward of the engine. The engine-gear is completely inclosed and the motion is transmitted from the crankshaft to the differential by the spur-gear in the reduced ratio of 3 to 1.

"The differential is of the spur type, which is preferred to the bevel type on the score of simplicity. The differential shaft carries the eccentrics for actuating the pumps, and to its outer ends are fitted brake-drums and also the chain sprockets. No change-gears or disengaging clutches are employed.

The Brakes and Their Application.

"Three independent brakes are provided. The first brake is operated by a foot lever and causes blocks to be applied to both sides of 18-inch drums fixed to each of the ends of the differential shaft. The second brake is actuated by a side lever which causes two segmental blocks to expand within a drum, bolted to each of the driving wheels; the brake load is balanced in a similar manner to the foot brake. The third brake is available in the engine, since by merely reversing the valve-gear a considerable resistance is offered to the movement of the car, even if steam is shut off.

Concerning the System of Lubrication.

"General lubrication of the engine and differential gear is by a system of pump circulation combined with an automatic dis-

tributing valve, supplying oil to each of the bearings successively. The engine and differential cases are combined, and a well fitted at the lowest point. Into this all the surplus oil drains from every bearing, and from it the oil is delivered by a force-pump into a circular valve-box connected with every bearing of the mechanism. To provide against the possibility of any of these distributing pipes becoming fouled or obstructed, a circular valve is provided which covers up all the outlets except one. This one therefore takes all the oil delivered by the pump. The distributing valve is slowly rotated by a worm gear on the differential shaft, the oil is automatically transferred from one bearing to another, and the possibility of stoppage is avoided. The system has the important advantage of taking out of the hands of the driver the responsibility for attention to lubrication, particularly for the high-speed mechanism.

"Owing to the temperature of the steam a high grade of hydrocarbon oil must be used for the lubrication of cylinders and valves. The result of the author's experience has led him to adopt a system of force-pump feed. An aluminum box, forming the reservoir for cylinder oil, also contains two pumps, the plungers of which are forced down sharply at regular intervals by a cam-operated spring. There is no packing of any kind in the pumps, but the plungers are made a good fit. After the cylinder lubricator has been charged, no further attention to cylinder lubrication is necessary for 1,000 miles. It merely requires periodical inspection and replenishment from the engineer in charge of the garage.

Conclusions Deducted from the Test.

"The mileage done by the car in question is as near as possible 27,000 miles (7th October). The only replacements to the engine are: piston-rod bushed, crosshead guide bushes, piston-rod sleeves and piston rings. The total cost of materials comes to about \$8. The valves in pumps have never been ground or their seats touched. The lubrication of engine and cylinders has been most satisfactory and the automatic lubricators have given practically no trouble. The fuel consumption averages one gallon to 4 1-3 miles."

ROBERT L. DUNN'S WAR LECTURE.

WASHINGTON, D. C., Dec. 29.—A lecture complimentary to the Automobile Club of Washington through the courtesy of the Pope Automobile Company, of Washington, was given at the New Willard by Robert L. Dunn, the well-known war correspondent. The lecture consisted of notes on the Russian-Japanese war and was a connected pictorial narrative of the greatest conflict of modern times. In a very modest way Mr. Dunn told how he landed in the Orient two weeks before hostilities commenced and without waiting for credentials started for the prospective scene of operations, Korea. He landed at Chemulpo early in February, and by some strange freak of newspaper luck the war began under his very eyes with the landing of the first Japanese army and the destruction of two Russian war ships. Mr. Dunn was introduced by President Duvall. The programs were unique, being printed on Chinese paper, bound with a piece of straw rope to which was knotted a piece of Chinese money.

For the better protection of its extensive warehouses and docks at Huelva, in Spain, the Rio Tinto Copper Company has recently acquired a powerful and interesting gasoline motor fire-float, in which the vessel itself and the pumps for throwing the water jets are driven by this type of motor. The gasoline motor is of the vertical type with six cylinders, developing 60 horsepower, and drives a single screw propeller through a clutch and shaft. The pumps for discharging the jets are driven by the gasoline engine through clutches, and their combined capacity is 1,200 gallons per minute. Each pump supplies three hose connections on deck, capable of throwing 1 1-2-inch, 1 3-4-inch and 2-inch jets respectively, or the entire delivery can be directed into one swiveling monitor throwing one large stream.

JUST what standard of design would be followed in the evolution of the Thomas "Forty," or whether conventionality in this respect would be entirely departed from and something entirely original be produced, has been a matter for speculation ever since the announcement of the linking of the Thomas name with the new Detroit plant. Conjectures on the subject have suddenly been set at rest by the appearance of the new car—not merely as an advance model, but in numbers in the shape of cars already in the possession of their owners. When the plant was first put in operation last summer, a schedule of deliveries was outlined and this has been adhered to, resulting in the appearance of the new Thomas "Forty" in different parts of the country at the same time.

A glance at the car as well as its specifications shows that it is intended as a candidate for the ranks of that class that contains only too few representatives—the medium-priced touring car of high capacity, speed and power in comparison with its weight and cost of maintenance. This is evident from the fact that in complete running order, with a generous lamp equipment, the car lists at \$2,750. It is made both as a touring car and high-powered runabout, the chassis being substantially the same in both cases with the exception of those detailed changes necessary to fit it for the latter rôle, such as raising the gear ratio.

Motor Design.—It is at once evident that it has been the aim of the designer throughout, not alone

TOP VIEW OF THOMAS "FORTY" CHASSIS.

where the power plant is concerned, but the entire car, to along lines of extreme simplicity, a fact that is apparent at the first glance at the motor. It is plain that the combined experience of other makers has been drawn upon and their mistakes avoided, and this, together with the knowledge of what is most needed in such a motor, has combined to produce a power plant that has been reduced to its lowest terms and which possesses the advantages of extreme simplicity and ease of adjustment in a superlative degree. Thus the valves, valve mechanism, spark plugs with their connections and the carburetor are all centered on the right-hand side of the motor, making every part of the latter accessible by lifting one side of the bonnet. An interchangeable system of making the parts has been adhered to throughout, so that not alone the valves but pistons, connecting rods and all other parts are likewise interchangeable, a limit of variation of one-half-thousandth of an inch being maintained. Drop forgings of special steels are employed for the crankshaft and connecting rods and the best grade of iron obtainable for the purpose is used in the making of the pistons and rings. The piston pins are hollow and of large diameter, being clamped in the connecting rod end. All bearing surfaces have been designed of generous length and all the main bearings are interchangeable. They are of special anti-friction metal shaped under heavy hydraulic pressure, and while liners are furnished it has been found that the bearing

TRANSMISSION AND CONTROL LEVERS.

surface provided is so ample that adjustments are not required until after a lengthy period of use. All bearing caps are heavily ribbed to prevent distortion and four bolts are provided at the big end of the connecting rods instead of two as is usually the case, in order to permit of a more even adjustment of these bearings than is ordinarily possible.

An original and interesting departure from standard practice is embodied in the valve-operating mechanism, rendering the setting of the valves readily adjustable. Side thrust is eliminated by interposing a roller between the cam and the valve lift. This roller is carried by a light steel arm pivoted on the opposite side of the crankcase across which it extends. It is encased on top and upon this case the valve lifter rests. The cam strikes the roller directly, imparting a vertical motion to the valve lifter, thus avoiding side thrust and its wear. The opening and closing points of the valves may be readily verified by means of a pointer fixed to the crankcase in connection with the usual marks stamped upon the periphery of the flywheel. The aluminum crankcase is bolted to the frame horizontally instead of vertically, and the cylinders are given a one-inch offset on it in order to minimize the side thrust on the power stroke. The compression is 75 to 80 pounds and the motor delivers its rated output of 40 horsepower at a moderate speed.

Motor Accessories.—The carburetor is of the automatic compensating type with the usual float feed and has been designed to effect fuel economy as well as a minimum of necessity for adjustment. Following a tendency that has developed of late, the timer, which runs on ball bearings, is placed directly beneath the footboard, so that the raising of the latter makes it particularly accessible. The remainder of the ignition system consists of a four-unit coil on the dash with a set of accumulators as current supply and dry cells as a reserve. A bracket designed to accommodate any standard magneto is provided on the crankcase, directly in line with the pump shaft, so that fitting this form of current supply presents no difficulty whatever. Any magneto desired will be installed on the car as an extra.

For cooling, a radiator of the vertical flat tube type, which has been found to give such a high degree of efficiency, has been adopted. In the course of tests, the tubes of a radiator of this type have been expanded to several times their normal size, showing that it would not be damaged by freezing. The water is circulated by means of a centrifugal pump, gear-driven from the camshaft. The suspension of the radiator is unique in that no side supports are employed; it is merely bolted to a bracket beneath, which carries its weight, and is supported at the top by

a brace rod extending to the dash. In this way the twists and strains of the frame in traveling over bad roads are not communicated to it and one source of annoyance—that of a leaky radiator—is well avoided. A belt-driven fan running on ball bearings placed directly behind the radiator completes the cooling system. The fan belt is made adjustable by means of a single nut. Drain plugs are placed in the lowest part of the jackets so that the latter may be completely drained whenever this becomes necessary.

Particular attention has been paid to the matter of lubrication, with the result that a system that is at once highly efficient and extremely simple and certain in operation has been devised, even the casual observer noting the total absence of oil pipes on the exterior of the motor. The system consists of an oil well or reservoir in the shape of an auxiliary tank cast on the lower side of the crankcase, and an oil pump communicating with the main bearings of the motor, the whole being self-contained within the engine itself. As long as the motor is running, oil is being pumped from this supply well onto the main bearings, from which it overflows into the crankcase. Holes communicating with the reservoir or well are drilled in the crankcase at a certain height, thus insuring a constant level at all times, the oiling of the big ends and pistons being taken care of by the splash. A glass bull's eye is provided in the front end of the reservoir so that the amount of oil contained in the latter is evident at a glance. To further insure against any failure in the oiling system, the oil pump and the ignition timer are placed on the same shaft, any derangement of the latter that would cause the oil pump to cease operation also bringing the motor to a stop by putting the commutator out of commission. The timing and pump gears are all well inclosed and packed with non-fluid oil.

Transmission.—As the first step in the transmission of the power to the road wheels, an aluminum cone supported on a steel hub and with a leather facing backed by helical springs, engages the inner side of the flywheel. This conical clutch measures 16 inches in diameter and has been tested to hold more than the maximum output of the motor. The cone is ribbed

MOTOR OF THE THOMAS "FORTY" DISMEMBERED.

THOMAS "FORTY" SPEED CAR, WHICH DEVELOPS A GAIT OF 60 TO 65 MILES AN HOUR.

instead of being solid, in order to make it as light as possible, which, in connection with its small diameter, tends to overcome the faults of excessive inertia and momentum usually inherent in clutches of this type where insufficient attention has been paid to the matter of size and weight in their design. From the clutch the power is carried to the gearbox by means of a universal yoke or cross to allow for any relative movement between these two links in the transmission. In order to avoid the friction generated by the usual form of disengaging collar, this duty is performed by two steel rollers.

The gearbox provides three speeds forward and reverse and is operated on the selective system of gear changing, in connection with a novel system of control. This is made plain by the illustration, in which A is a hand lever rocking about B as a fulcrum, C being thus movable endwise by means of a flexible connection E between this shaft and the lever A. The finger F in the gearbox engages either of the sliding gear members at the option of the driver; a second D, also keyed to C, engages at all times the interlocking slide G, permitting gears to be shifted only when the clutch is disengaged. The spring H holds the lever A when in neutral in such a position that the movement forward gives the intermediate or usual starting speed, while a backward movement throws in the direct drive or usual running speed. It is thus only necessary to move the lever H sideways from neutral against the tension of the spring to obtain either the reverse or low speed. The gears and shafts are of nickel steel, running on American roller bearings; stuffing boxes are employed to make the case oil-tight. A standard type of propeller shaft with universal joints at each end constitutes the connecting link between the gearbox and the rear axle. The universal joints are inclosed in leather casings and run in heavy grease, while the propeller shaft is made of a high-carbon steel.

Running Gear.—The rear axle is of the Timken semi-floating type and Timken roller bearings are used throughout the running gear. The front axle is a single piece I-beam drop forging of steel with the cross bar connection of the steering gear, which is of the screw and nut type, placed back of it. This provides protection for the latter when meeting light obstructions and is a safeguard against accident due to a deranged steering gear arising from such a cause. The suspension is of the semi-elliptic type both front and rear, the latter measuring 52 by 21-4 inches and the former 36 by 2 inches. A pressed steel frame of the usual channel section is employed, with a subframe dropped 4 inches for the support of the motor and transmission. A steel plate is riveted between the main and subframes, forming a portion of the scheme of dustproofing the entire mechanism and adding a continuous stiffening effect throughout the entire length of the subframe, which extends for almost two-thirds of the length of the car. The wheels are 34 by 4 front and rear for

touring service and 34 by 3 1-2 front on the runabout, this being the only difference between the two other than the change in the gear ratio already mentioned. Extending beneath the entire mechanism a sheet steel dust pan the width of the subframe is placed. An ingenious clip permits its instant removal. The wheelbase is 112 inches and the tread standard, the touring body having a seating capacity of five. The weight is 2,550 pounds.

Brakes.—Realizing the great importance of this part of the car, its designer has gone to unusual pains to provide a braking equipment of more than sufficient capacity to take care of every emergency. Two sets of brakes are employed, the first or transmission brake, used for ordinary running and operated by a pedal, and the emergency brake, which is of the internal expanding type, is located in drums on the rear wheels. They are effectively encased in a steel housing to protect them from dirt, adjustments readily being made through the hand hole provided for that purpose. The transmission or foot brake consists of a 10-inch sheet steel band, with a 3-inch face, acting upon a steel drum bolted to the propeller shaft universal yoke. This band is lined with camel's hair felt, making it particularly effective. The suspension of this brake is worthy of mention in that a very simple and effective method of accomplishing this has been employed, which at the same time provides against the possibility of the band dragging when not in use. The spring shown in the illustration of the brake serves to hold it out of action when running.

HOW THE REAR AXLE LOOKS WHEN DISMOUNTED.

CARE OF THE IGNITION STORAGE BATTERY

By H. GERNSBACK.

IT is probably not realized by many autoists that over 80 per cent. of American gasoline automobiles are equipped with storage batteries for ignition, and a few hints on how to handle and care for such a battery will, no doubt, be welcome to the user. It is not the object to go into mere technicalities nor to explain the theory of the accumulator, but rather to state how to avoid a great many mistakes which have come under the observation of the writer. A storage battery of any make is a very complicated piece of electrical apparatus and has to be treated accordingly in order to obtain satisfactory results from it. The automobile manufacturer, who usually buys the battery with which he equips his cars, does not always find the time to go into details concerning batteries, and the owner of a new automobile should convince himself that the battery is up to its standard, fully charged and free of corrosion, before he puts out for a long trip. He should always bear in mind that there is no storage battery made which will hold its charge for over two months, and a new car that has been standing in a salesroom for a long period will be found not to work satisfactorily, or frequently not at all, if the battery was not kept charged properly. The general tendency is then to condemn the battery, which might be the best in the world, but if it is not kept in a state of usefulness by proper charging and care, its efficiency is totally destroyed.

Inspecting a New Battery.

A new battery should be first inspected to see if it has enough acid (electrolyte). To do this, unscrew the vents, or plugs, which are usually located in the center of each cell. The liquid must, under all circumstances, cover the plates, which can be seen by looking through the opening of vent tube. Should this not be the case, *distilled* water should be poured in each cell until the liquid stands at least one-fourth inch over the top of plates. It is not necessary to add acid, as only the water evaporates. The remaining solution, therefore, becomes denser and denser, and when distilled water is added the electrolyte will be brought up again to its proper specific gravity. Ordinary water should never be used in a battery, as even small quantities will invariably prove disastrous. If distilled water cannot be obtained, clean, filtered rainwater may be used to good advantage. The user should never attempt to take a long trip without previously testing his battery and a double test, which the writer never has known to fail, and which is described below in its essential details, ought to be made.

This comprises a voltage reading and a "sparking" test. Every cell should be tested individually by means of a low-reading voltmeter (0-3 volt) and as long as a battery shows 1.9 volts it will be found good for a 50-mile run. This voltage reading must be made while the engine is *running*, as a battery at rest will not give a correct reading, due to the recuperation. It is a well-known fact that an accumulator will show 1.9-2 volts per cell on open circuit, even if it was totally run down previously. As soon as the circuit is closed, however, the voltage will fall to 1.5-1.0 inside of half a minute. This property tends to mystify the layman a good deal. The "sparking" test must be done carefully and not oftener than absolutely necessary. As it is nothing but a dead short-circuit, which of course does not tend to improve the battery, the writer would not recommend the method if a better one were known; if, however, one is a little careful no damage will ever arise.

How to Test the Cells.

Procure a piece of insulated wire of 12-gauge about 8 inches long and scrape off the insulation at both ends for about one-fourth inch. Place one end of the wire firmly on one of the end binding posts of the battery; with the free end of wire touch the other end binding post rapidly in such a manner that the contact will

not last longer than a fraction of a second. A loud, snappy, blue spark will be the consequence if the battery is well charged. If not, the spark will not be loud nor bright.

The writer does not recommend the use of an ammeter, for the purpose of investigating the total amperage of battery; ammeters are usually wound with such a low resistance that when a test is made, which in order to be fairly accurate has to last for about five seconds, directly short-circuits the battery. If this is done often it will ultimately ruin the battery, due to scaling and bending of plates. The "sparking" test also helps to find troubles which could not have been found with the volt meter alone. For instance, the writer often saw batteries which tested up properly in voltage but which could not be made to run the coil nor incandescent lights. The "sparking" test was applied, but without result. It was found that either corrosion had taken place, the connection bolts were loose, or oxidized, or else a lug which connects the plates was broken. After these troubles had been remedied the battery worked again as well as before.

When a Cell Is Fully Charged.

A freshly-charged cell should register 2.20-2.25 volts on open circuit and from 2.10-2.15 when the engine is running at high speed. From this point the voltage soon drops to 2.00, and from there very slowly to 1.90. In fact, three-quarters of the discharge lies between these two points. When the voltmeter once registers 1.80 volts the discharge should be discontinued, as at this point the coil will stop working abruptly, which is a hint to have the battery recharged at once. To get the maximum mileage from a battery the coils must be so adjusted that they take a minimum of current. No benefit is ever realized by forcing 4-5 amperes through a coil; in fact, it is detrimental to the platinum points, to the coil itself, to the timer, and to the spark plug. A four-cylinder coil should never take more than 0.75 ampere, when the engine runs at full speed. In order to achieve this, turn back all the vibrator thumb-screws in such a way that the tremblers just work without the engine missing fire. If once adjusted the coils should not be touched for the season, and one will get a good idea of the efficiency of the battery.

The average sparking battery, if well constructed, should last from three to four years, if it is treated properly, which means recharging it every three weeks, no matter if run down or not; even if it stands idle a charge should be given to it every four weeks, otherwise the plates will become sulphated (coated) very soon, greatly reducing the efficiency of the cells. To keep metal parts from corroding they should be coated with vaseline once a month. In order to prevent the battery from being thrown around in battery box, put some shock-absorbing material, such as machine waste, excelsior, or the like, under, and around the sides of the igniter. This will prevent it from breaking and from being damaged internally.

PASSING OF THE NAME "CHAUFFEUR."

It would appear that that ill-chosen Gallicism "chauffeur" has been doomed to be consigned to oblivion. England and America are agreed for once on the use of the same word to designate the same thing and that word is driver. By an imperial edict Germany has let it be known that she will have none of it; her chauffeurs will henceforth be "wagenfuehrers," and where there are two one will be the "hauptwagenfuehrer" and the other the "unterwagenfuehrer"—a generous mouthful in either case, but not disturbing to a Teuton. Even France has gone back on her own choice, for the average Parisian now prefers "mecanicien" to designate either the driver or his assistant, from which it is apparent that chauffeur will sooner or later be relegated to the limbo of forgotten terms.

LETTERS INTERESTING AND INSTRUCTIVE

The Necessity for Intelligent Valve Grinding.

Editor THE AUTOMOBILE:

[520.]—Will you please tell me through "Letters Interesting and Instructive" how to grind the valves of an automobile engine and how to know when such grinding is necessary? Is it not possible to make an engine with valves of a type that would not require grinding? I cannot understand why, if valves are properly fitted and the engine is kept working under proper conditions, it will be necessary at such frequent intervals to regrind the valves. Any light you can throw on this subject will be greatly appreciated.

City Island, N. Y.

JOHN WILKINS.

Valves need grinding, because it is impossible to protect them from the wear that necessarily occurs on certain portions with all moving mechanisms. Even by the use of the best steels, it is impossible to provide a quality of material that will indefinitely resist the scoring action of the rapid flow of gases, together with the corrosive action due chiefly to their high temperature. Added to these is the chemical action of water or other minor components of the mixture, and the continuous hammering when the valves are in action. When the full force of these various destructive effects is realized it becomes a wonder not that valves wear out but that they last as long as they do. By careful designing most of the injury is made to occur at points capable of being readily resurfaced by the process of grinding. To grind a valve it is necessary to apply a small quantity of fine abrasive material between the valve and its seat, following this by rotating it with a screw-driver, brace, or any convenient means, until the faces in contact are bright and smooth. Almost any abrasive may be used, even sand from the roadside having been utilized in an emergency, but with the harder abrasive such as emery and carborundum it is very essential that all traces of the grinding material be removed after the work is completed, since otherwise they will cause wear in the cylinders. Some experts prefer to use ground glass, grindstone dust, and the like, because of this point. The need of grinding is indicated by lessened power, due to leakage of the gases through the valves; by unusual ease of cranking; by backfiring into the carbureter, and by the condition of the valves themselves, in respect to pitting, corrosion, and incrustation.

Carbonized Cylinders and Air Cooling.

Editor THE AUTOMOBILE:

[521.]—Is it a fact that the cylinders of an air-cooled engine carbonize inside at frequent intervals, so that they have to be removed and the pistons taken out to scrape away the carbon? Is this the real and serious objection to this type of motor? I am told that this is the case and would greatly value your opinion.

Barberton, Ohio.

WILLIAM WALTERS.

With some types of air-cooled motors, not as well designed as they might be, there undoubtedly exists the tendency to which you refer. In such cases carbonizing occurs in a combination of the high temperature and the undue quantity of oil used, the surplus oil being burned imperfectly because of the lack of sufficient cooling means, with the result that it is deposited in the manner you mention. When such deposits reach a certain amount there is, of course, nothing for it but to take the engine down and give it a thorough cleaning. The necessity for this is generally indicated by the frequent occurrence of preignition, due to projecting points of red-hot carbon within the cylinder. With the best and most successful air-cooled motors of to-day no more oil is required than with a water-cooled car, and overheating is little, if any more, likely to occur, especially in the hands of a competent operator. It must be remembered that even with the best systems of water cooling it is possible, through careless operation or defects in design, to have carbonizing occur to a very serious extent. Carbonization of oil in cylinders, therefore, is something liable to occur in both water-cooled and air-cooled cars.

Anti-Freezing Solutions for Water-Cooled Cars.

Editor THE AUTOMOBILE:

[522.]—In the issue of "The Automobile" of December 6, I note a short article on non-freezing solutions for automobiles, in which the experience of readers was invited. I have made some experiments along this line, and gave the results to the local paper for the benefit of fellow automobilists in the town. As the results in the form of data will, in all probability, be of value to owners of cars in other parts of the country, you may reprint them if you wish to do so.

C. F. NIXON, Ph.G.

Leominster, Mass.

The fluids recommended are solutions of calcium chloride, glycerine and wood alcohol. I made a 10, 15, 20 and 25 per cent. solution of each of these and determined the freezing point of each, with the following result:

Calcium chloride—Ten per cent. solution freezes at 15 above zero F.

Calcium chloride—Fifteen per cent. solution freezes at 5 above zero F.

Calcium chloride—Twenty per cent. solution freezes at zero F.

Calcium chloride—Twenty-five per cent. solution did not freeze at zero.

Wood alcohol—Ten per cent. solution freezes at 15 above zero F.

Wood alcohol—Fifteen per cent. solution freezes at 5 above zero F.

Wood alcohol—Twenty per cent. solution freezes at 2 above zero F.

Wood alcohol—Twenty-five per cent. solution freezes at zero.

Glycerine—Ten per cent. solution freezes at 20 above zero F.

Glycerine—Fifteen per cent. solution freezes at 15 above zero F.

Glycerine—Twenty per cent. solution freezes at 8 above zero F.

Glycerine—Twenty-five per cent. solution freezes at 5 above zero F.

Zero Fahrenheit was the lowest point I could reach with my freezing mixture. This is, I believe, low enough for practical purposes, as these higher percentage solutions freeze mushy, and not solid. They would not, therefore, in my judgment, expand enough to burst the parts if they did freeze in the machine.

I have in my machine a mixture of one part each of wood alcohol and glycerine and two parts water. I do not believe that this will freeze above 10 below zero. As shown above, a 25 per cent. solution of calcium chloride stands the lowest temperature, but is objectionable, as it is likely to corrode the parts with which it comes in contact. Wood alcohol will evaporate by the heat of the engine and more must be added at intervals. Both glycerine and wood alcohol are likely to soften rubber connections after a time, but this would be a small matter.

Some Questions Concerning Fuel and Ignition.

Editor THE AUTOMOBILE:

[523.]—Is there any advantage in the distance from the carbureter to engine? Will a carbureter give the same service with a long pipe to engine or bolted direct to cylinder? Which of the two patterns of installations would make the engine start easier? Should the float in a float-feed carbureter be set so the gasoline will stand up as high as possible without running over at the spraying nozzle, or slightly below the top of nozzle? Why is it that the air-valve springs in carbureters for single-cylinder engines are made large in diameter with but few coils, while for multiple-cylinder engines the air-valve springs are small with several coils? Will a carbureter made for a four-cylinder engine give satisfaction on a single-cylinder, both engines having the same size inlet pipe? How is the proper way to adjust a vibrator, and how do you tell when it is adjusted properly?

Flemingsburg, Ky.

A SUBSCRIBER.

While there is some difference of opinion as to which of the two methods you describe really constitutes the better practice, a majority of designers seem to be in favor of getting the car-

bureter as close to the inlet valves as possible. With a long pipe, it is obvious that there must be a certain amount of attenuation of the air upon suction, with the result that the carbureter is not brought as instantaneously into operation as might be desirable. On this account the Renault people have even patented a system of feeding fuel by means of four carbureters—one for each cylinder. On the other hand, there is one school of engineers that insists upon a certain advantage supposed to be inherent in the long piping, it being claimed to act as a sort of reservoir for mixture, so that it is not necessary that the carbureter be brought instantly into action, there being enough fuel in the intake piping to provide several charges. On the 1907 six-cylinder Panhard cars a scheme of this sort is applied, it is said, with good results. There are so many factors concerned in the starting of an engine that it is difficult to give a conclusive answer to your third question. If the engine had not been stopped long the mixture contained in the long intake piping might cause it to start very easily; while if the motor had stood for some time it would seem that the carbureter close up would be the idea. A float-feed carbureter should be so set that the gasoline will stand about a sixteenth of an inch below the top of the atomizing nozzle. This will require that the level maintained in the float chamber be fully a quarter of an inch lower still, because of the capillary attraction in the small bore of the nozzle. Even with the fuel very low, however, it is surprising how the suction of the engine will draw it out. We do not think that it is a fact that air-valve springs vary in the way you state, except in isolated instances. A small diameter-spring, with several coils, however, is likely to act more quickly than the other kind, which might be of advantage with the more steady work entailed in feeding four cylinders. A carbureter suitable for a single cylinder of given size should feed four cylinders of the same size equally well. The reason of this is that four cylinders do not overlap in their demand on the carbureter, but require fuel one after another. They thus keep the carbureter working more constantly, but do not make any greater demand upon it than a single cylinder. The adjustment of vibrators is difficult to explain without taking up considerable space, and can be learned most effectively by experimenting until a good, hot spark is obtained between the plug terminals under normal working conditions. The sound is less of a guide than is commonly supposed. A good deal of information on this subject was given in THE AUTOMOBILE, issue of November 15, 1906, in answer to question No. 467.

Another "Hardy Annual" Crops Up Again.

Editor THE AUTOMOBILE:

[524.]—I have an argument on hand at present, and it is one that you have probably had before you more than once in the past. A claim that an automobile going round a curve at a very high rate of speed, such as on a track, for instance, will upset toward the inside of the track. I hold, that if it turns over, it will go in the opposite direction, and base my claim not alone on theory, but on experience. Any moving object which, when going in a certain direction represented by a straight line, is suddenly turned from its course, tends to continue in the original direction, and centrifugal force, in the case of a car, will cause it to turn over outwardly or away from the track fence. I am certain that your explanation will not only settle the argument in my favor, but will also make the matter clear to many another.

Bronx, N. Y. City.

JAMES REUTERSHAN, JR.

This is, indeed, one of the hardy annuals in the way of questions on an elementary principle of mechanics; no matter how often it is answered it continues to crop up again and again, and usually in about the same form. Automobile racing in particular has served to give it a new lease of life. Of course you are right. It would be about as erroneous to state that a blazing pinwheel throws its fire toward its center or hub, when revolving at a high speed, as to say that an automobile tends to overturn inward when rounding a turn at sixty or seventy miles an hour. From one cause or another, automobiles have upset toward the infield of the track during the course of a race, due to colliding with an obstruction, defective steering gear, or something of the kind, and

probably this has given rise to the general assumption in question. When a body traveling in a straight line at high speed changes its course two forces come into conflict—gravity and centrifugal force. If the speed of the object be so great, and the radius of the curve so short that centrifugal force overcomes the attraction of gravity, the object will leave the ground and tend to fly in the direction it was originally traveling. In the case of a car the inside wheels would leave the ground and the car somersault sideways toward the outside of the track. This has been illustrated in automobile accidents time and again, such as that on the Florida beach two years ago. It is in order that the attraction of gravity may always be superior to centrifugal force that railroad curves and race tracks are banked. This shifts the center of gravity to the inside wheels of the car and prevents it from overturning outwardly, as would be the case were a curve taken at high speed on the flat.

Peculiar and Unusual Fan Trouble.

Editor THE AUTOMOBILE:

[525.]—I have a small four-cylinder water-cooled car, the cylinders of which are commencing to show a great tendency to become overheated. The radiator is the usual honeycomb pattern, with fan behind it, and the cooling system holds five gallons of water. Whenever the car is run hard for a short time, the water boils and overflows, while the cylinders get so hot that I am afraid of the pistons scoring them, through injury to the lubricant. I can find no obstruction in the cooling system, and the water seems to circulate freely, the pump being apparently in good order.

Altoona, Pa.

ALFRED JADWIN.

Unless there is some obstruction or deposit in the waterjackets, so located as to prevent the free circulation of the water to other portions of the cooling system, it would seem probable that there is something wrong with the air blast through the radiator. Of course, heating may occur with a great many cars if the engine is run hard for long periods, with the car standing still but if this is not your trouble, and the trouble has come on simply in the course of ordinary use, it cannot be thus easily explained. We have known of cases in which the fan blades became bent, and by running too nearly flat failed to set up the blast required, despite their rapid rotation and the fact that everything else appeared to be in perfect order. A thorough investigation along some or all of the lines suggested should disclose the difficulty. Pay particular attention to the condition of the fan, as suggested, especially if it be of the type in which the blades are not shrouded together by some sort of peripheral member.

WHY MR. HOTCHKIN COULDN'T DEMONSTRATE.

Editor THE AUTOMOBILE:

[526.]—It is with pleasure that I inform you of the conviction of Willie Parker and Harry Stein, who stole my 1906 Packard demonstrating car from in front of the First Regiment Armory, on the opening night of the Auto Parts Show, September 22, 1906. They were sentenced December 19 to one year's term in the county jail, each. They have already been in jail about three months, awaiting trial. This makes the jail term about fifteen months for them. Parker comes of a good family, his father being an ex-vice president of the Chicago Board of Trade. He has been in several scrapes before. Harry Stein is now wanted by the New York City police for theft of automobile parts. It is more than likely that these boys would have been released with a reprimand had I not instructed my attorney to proceed against them. They are members of a gang of automobile thieves and are both implicated in the theft of Messrs. Gardner, Fairbanks, and Corder's machines, from this city. They also have confessed to the theft of several other machines, and it was high time that a check was put on this kind of business.

With my own machine, they ran, as near as I can find out, in three days, about 700 miles, and succeeded in wrecking it to such an extent that it cost me in the neighborhood of \$300 to have it repaired. Visitors at the Parts Show thought it was a bluff on my part, when I announced that I could not make demonstrations on account of the theft of my demonstrating car.

Trusting that this may be of some service to you as a news item, and that you will be kind enough to straighten up the matter set forth in the last paragraph, I am,

P. M. HOTCHKIN.

Chicago, Ill.

(Continued from pages 911-914, THE AUTOMOBILE, December 27.)

THE milestones bordering the French roads, or rather the *bornes kilométriques*, are exceedingly well placed, legible, and accurate. They mark the distance, on the great trunk roads leading out from Paris, from the capital to the other termini, "Routes Nationales" Nos. 10 and 12 Paris—Brest, via Versailles, Alençon, and Rennes; "Routes Nationales" Nos. 13 and 172, Paris—Coutances, and the Route de Nantes, via Versailles, Chartres and Le Mans.

Besides showing the kilometerage, they note also the class of route, its official number and, when a stone is on a boundary between one département and another, their respective names. On the minor roads this information is no less clear and explicit, but the distances are usually reckoned as from one *chef-lieu* (county town) to another.

One Can't Go Astray in France.

if he knows the plan and procedure on which these kilometer stones have been laid down; and if he travels along a navigable river, in the now facile and popular canot-automobile, he will find the river bank marked off in the same way, except there is a little white stone each hundred meters (ten to a kilometer). This is that you may not be over charged if you have recourse to a towboat. You pay for *remorquage* (towing) by the kilometer, hence some sort of official reckoning was made necessary. France is paternal all the way through, and she does not neglect the roads and their users, or *les chemins qui marchent*, as Pascal called the great rivers.

The other road markings in France are even more thorough and detailed than the kilometer stones, though the distances as given by the two classes of markings do not always correspond. It depends upon whether the distance is reckoned from the center of the *ville* or the edge or boundary of the *commune*, and again as to whether a road has recently been straightened or not. This accounts for the occasional discrepancies between the little blue painted, cast iron signs which are at every cross roads and the figures given by the kilometer stones themselves—this, and the fact that often, since the kilometer stones were first planted, a road has been straightened here and there and a kilometer has been saved in the distance.

All these are governmental affairs. Then come the most excellent road markings of three private organizations: the Automobile Club de France, the Association Générale Automobile, and

The Omnific Touring Club de France.

which, with more than a hundred thousand members and the President of the Republic as its patron, is doing a wonderful work in all things appertaining to "le tourisme" in France, whether one travels by road or rail, by an automobile boat on the water, or a land automobile, or for that matter, by balloon or aeroplane.

The Touring Club de France is plentifully besprinkling all the main roads with great painted signs giving the terminus of the route, the town through which one is passing momentarily (Good idea, this!), and the next town or city in either direction, with their proper distances, all marked in great staring letters at least four inches high, so that one may read literally as he runs—and this, be it remembered, is what the automobilist likes. As the new locomotion makes headway in France all things apparently strive to keep pace with it. This, more than all else, accounts for the supremacy of France in automobilism to date.

Coupled with the above mentioned excellently planned and placed signs, are still others denoting that an important town lies a certain distance just off the main road, or that a natural curiosity, a fine viewpoint, a cascade, a chateau, or a Roman ruin are but a half a kilometer away.

All this makes for enjoyable travel by road, and gives the stranger the benefit of an intimate acquaintance with the land so far as his finding his way about goes. One must know how to read all these signs, and where to look for them, and be possessed of a nose for topography, as the French have it, nevertheless.

The Association Générale Automobile.

goes farther and marks danger spots in a striking and efficacious manner by a series of staring black and white painted iron plaques, with no wording thereon, but with a series of cabalistic signs which even a Digger Indian or a Sioux could understand without being told. I understand the Vanderbilt cup commission used these signs on the Long Island cup course and that they proved highly satisfactory.

A simply drawn or silhouetted gateway means that a level railway crossing will be met with soon; an archway with a passage beneath, that the road passes beneath a railway; and a sort of great inverted U indicates a culvert or *caniveau* across the road (most welcome, this!). Finally there is a little nondescript thing, like the hump on a Bactrian dromedary, which indicates the nearby presence of a *thank you, ma'am*, known in France as a *dos d'âne*, or donkey's back.

There Are Other Signs.

and signals that the traveler on the roads in France meets with once and again, and is glad he does. One is a white lettered sign on a blue ground stating that a half a kilometer farther on

CHEMIN DE GRAND COMMUNICATION.

ROUTE NATIONALE AT THE COTE DE GAILLON.

ROUTE DEPARTEMENTAL IN NORMAND

the route is in *en course de réchargement*, meaning that there is road repairing going on; this is well to know before you come suddenly upon it. A similar sign announces that a steam roller is at work; this, presumably, is for the benefit of horse-drawn traffic.

There is another class of signs—and this is all—those put at either end of a straggling village or town restricting the speed of automobilists to twelve, ten, eight, or even six kilometers an hour while passing through—the speed that the local *maire*, who most likely is a *bon bourgeois*, or even a peasant farmer, who never rode in an automobile in his life, thinks is proper. Sometimes one is held down to *au pas* (a walking pace), and whenever one meets with one of these warnings he had best take it to heart, for the local authorities can be very severe when they like, even in France. It is all well meaning and well done in many cases, for a narrow, twisting cobblestoned main street in an unknown French town has untold horrors for a stranger automobilist, even if he is adept.

ROMAN MILESTONE IN PROVENCE.

Road obstructions are not unknown in France, but the law is very strict against one's taking up more than his proper share of the road. If you overtake a slow-going vehicle it must make way for you and let you pass. Even with the peasant road user this is not mere idle theory or an unused law, as it frequently is in England, where a motorphobe will often not get out of your way, even if you threaten to have the law on him.

The law is summary in France, with contravention against the rule of the road, as with other minor offenses, though it is true that bureaucracy oftentimes clogs the wheels. Once when

We Had Been Struck by a Market Wagon,

which tore our front mud guard off its supports, we were interrogated by a couple of anxious-to-please gendarmes, who were equally anxious to make a *procès verbale* against a poor, well-meaning Norman *paysanne* who was driving her cart to market loaded with butter, eggs, and fowls, to say nothing of a bleating calf. She meant no harm, and the damage was really slight, and we were not in the least vindictive. In spite of this, the action of the gendarmes showed at any rate they bore known no illwill against *les étrangers* and didn't suggest for a moment that the case might be turned against us. How different! Oh how different, might have been the case in England!

The two gendarmes simply sprang up from nowhere—they were not in sight previous to the *tamponnement*—and they simply filled their notebooks with pros and cons that they might have something to show their brigadier as a result of their morning's work. The old lady was, as natural, scared half out of her wits and we ourselves—this being the first experience of the kind in some years of automobile travel—were something more than curious, perhaps even excited. The only cool persons, in fact, were the two gendarmes of the nationality which is usually accounted the most excitable of all races, unless it be the evil-eyed Sicilian.

The interrogatory of the old lady being finished, the gendarmes turned to us—we were four, the author, the artist, and two in the tonneau.

Our *papiers* were demanded, produced, and found in order. (The first thing an

automobilist is asked for by an "agent" or a "gendarme" in France is his *papiers*. Verb sap: Have them always handy.) Our addresses were then noted, and then the driver was asked his age, birthplace, and—of all things—"Quel est le nom de votre merc?" Why this, we expostulated? "It is for your good," said the brace of courteous gendarmes in chorus.

Was there ever a law so completely polite in its procedure! All was given that was asked for, and all of us went on our ways rejoicing; the old woman thankful that she had not been called upon to pay up; the gendarmes grateful for something to break into their monotonous existence; and ourselves that we might take to the road again and make up for lost time.

The French Peasant Knows the Law

very well, and observes it, though he may have a natural resentment for the dust you throw up in passing. This is human nature. Everyone keeps to their right as a matter of course, and everybody in France is exceedingly careful in taking corners—all but the drivers of butchers' and bakers' carts in suburban Paris, who are the same as their reckless brethren everywhere else.

Stray cattle, and even dogs, have no rights on the roads, and if you bowl one over there's no damage to be paid for by you if you were not otherwise reckless, and you even have a redress against the proprietors of the beasts if they have caused you damage. In some parts grazing cows by the roadside are invariably held by a cord. This is the case in Normandy, but in Brittany they always have a guardian with them, an incompetent little Breton peasant maid in *sabots* and *coiffe*, who loses her head immediately you heave in sight, and deserts her charges, leaving them to your tender mercies, which are, of course, gracious and gallant. One could not take advantage of one of these winsome and theatrical looking little samples of Breton femininity.

Speaking of Brittany Suggests

that it is there that one meets a most unusual puncture fiend in the shape of *sabot* nails. They have a way of dropping out of the wooden shoes affected by all classes in the Breton countryside, and resting point uppermost all over the ground. So numerous are they that one has only to scratch the earth, anywhere between Nantes and Quimper and Mayenne and Brest, to gather a handful of these exceedingly vicious hobnails. There's only one remedy, and that is good heavy tires that they won't puncture; then every night you simply run your hand over their peripheries and pull out a half dozen, a dozen, or twenty of these sharp pointed, big headed nails—that's all.

Just for the Sake of Comparison

it is interesting to stop and consider what travel in France was a hundred years ago, particularly for the foreigner, usually the Englishman, who came over the same road that De Warde and Buckingham took in the time of Louis XVI. A hundred years ago it cost nearly five pounds sterling, which is not greatly more than it does today, and the journey was first made by coach from London to Dover, and then by a cranky little shallop across the Channel to Calais.

Next morning the Paris coach left en route for its final stopping place in the French capital. The average speed was four miles per hour and 54 hours were consumed in this part of the journey.

SOME OF THE ROAD SIGNS OF THE TOURING CLUB OF FRANCE.

CLUBS START NEW YEAR WITH SOMETHING DOING

Massachusetts Automobile Association Transacts Business.

BOSTON, Dec. 31.—The board of directors of the Massachusetts Automobile Association held a meeting recently at which plans were discussed for the management of the association under the new rules of the American Automobile Association. According to the new rules Massachusetts will be entitled to four representatives on the board of directors of the A. A. A., and it is expected that the State association will become of much more consequence than has been the case heretofore. The directors decided, in view of the increased work that will fall to the officers of the association, to divide the office of secretary-treasurer, and James Fortescue, secretary of the Bay State Automobile Association, was elected secretary, and J. C. Kerrison treasurer. The directors have nominated as representatives of the Massachusetts Association on the board of officers of the A. A. A. President Elliot C. Lee, of the Massachusetts Automobile Club; President Lewis R. Speare, of the Bay State Automobile Association; President John P. Coughlin, of the Worcester Automobile Club, and President J. L. Haynes, of the Springfield Automobile Club. The Massachusetts association has over 1,600 members, and now has six representatives on the A. A. A. board. A campaign will be made in this State to secure individual memberships in the A. A. A. as well as the customary club memberships.

Quaker City Motor Club Adopts Constitution.

PHILADELPHIA, Dec. 31.—Over 150 of the 235 members of the Quaker City Motor Club attended last Thursday night's meeting at the club's new quarters in the Hotel Majestic, when the constitution and by-laws, after a three-hours' revamping, were finally adopted. The nominating committee submitted a long list of candidates for permanent officers, the names of some of the best-known men in local, professional, and business circles being included. The election is scheduled to take place at the next monthly meeting. Formal application was made to-day under the laws of Pennsylvania for the incorporation of the club. The club is making active preparations for a big campaign of endurance runs, race meets, hill climbs and parades during the incoming year of 1907. The endurance run to Harrisburg on New Year's Day is the initial one on the schedule.

Inter-City Bowling by Massachusetts Automobilists.

WORCESTER, MASS., Dec. 31.—Representatives of the Worcester Automobile Club and of the Bay State Automobile Association of Boston met to-day and arranged for a series of bowling matches to be held this winter between representative teams of each organization. The first match will be in Boston January 24 and the next in this city on January 31. The matches will be held every week, alternating between the Hub and the Heart of the Commonwealth. Both clubs will contribute a silver trophy, to be chosen later, which will be awarded to the winning team. Mr. Weltman will captain the Worcester team. He says some of the members need exercise and will get it before the advent of the spring season.

Automobile Club of Buffalo Elects New Officers.

BUFFALO, N. Y., Dec. 31.—At the annual election of the Automobile Club of Buffalo the following board of officers was elected for the current year: President, Seymour P. White; vice-president, Frank B. Homer; secretary, D. H. Lewis; treasurer, D. M. Satterfield; board of directors, the above-mentioned officers and E. R. Thomas and Charles Clifton. The retiring president, H. A. Meldrum, was presented with a beautifully-designed loving cup, and W. H. Hotchkiss made an address on new legislation pertaining to the use of automobiles.

Automobile Club of America Moves Its Executive Offices.

NEW YORK, Jan. 1.—The executive offices of the Automobile Club of America were removed on Monday, December 31, to the new clubhouse on Fifty-fourth street, west of Broadway, where in the future all of the business pertaining to the club will be transacted. The new building will not be open for the use of members until its final completion, of which due notice will be given. Jefferson M. Seligman has been appointed chairman of the club's sign-post committee, and touring members who may note the desirability or necessity of placing directing signs on the road in various localities are requested to communicate with Chairman Seligman.

A committee on public safety, consisting of the four ex-presidents of the club—Winthrop E. Scarritt, chairman; George F. Chamberlin, Albert R. Shattuck, and Dave H. Morris—was appointed by the board of governors at its meeting December 28. The committee will consider ways and means whereby the club may better use its power and influence toward correcting certain evils which have grown apace in connection with the evolution of the sport and industry, and will act with the law committee in recommending to the legislature such changes and amendments as may seem necessary for the better protection of all users of the highways, and take a determined stand against speed madness by the reckless owner or the inconsiderate dare-devil chauffeur. An address on the purposes and aims of the committee will soon be issued.

Bay State Automobile Association Has a Christmas Tree.

BOSTON, Dec. 31.—The annual meeting for the election of officers of the Bay State Automobile Association and for such other business as may come before the meeting, will be held on Monday, January 7, at the clubhouse, 282 Dartmouth street. During the year the club has occupied its new clubhouse and has gained materially in membership. It has been very active in all lines, among its events being the spring race meeting at Readville track, the tour to the White Mountains in the summer, and the gymkhana games this fall, besides several short tours to Rye Beach and other places. A new feature of the association's activity established during the year has been the dining service at the clubhouse. This has been well patronized by the members and is a pleasant part of the club's life. The club is to celebrate New Year's as usual, but instead of a run to some place at a distance, as has been the custom, the celebration will take place at the clubhouse and will include a dinner and entertainment. Saturday evening there was a Christmas tree with appropriate gifts to all who were present. Secretary James Fortescue was remembered by Santa Claus in a substantial manner.

Long Island Automobile Club Selects Committees.

BROOKLYN, N. Y., Dec. 31.—The regular monthly meeting of the Long Island Automobile Club was held last Wednesday evening at the Cumberland street clubhouse. Some slight amendments to the by-laws were adopted and standing committees for the coming year were selected. Dr. A. C. Howe heads the garage committee as chairman. The house and entertainment committees have been combined under one head, and the chairman is Frank G. Webb. L. T. Wise again heads the technical committee. The membership of the club numbers 400.

Rhode Island A. C. Elects Officers on January 9.

PROVIDENCE, R. I., Dec. 31.—The annual meeting and banquet of the Rhode Island Automobile Club will be held at the Garnet street clubhouse on the evening of January 9. E. A. Rusden, a well-known member of the club, sails on January 8 for a trip around the world, part of which will be by automobile.

Progress of the Self-Starting Device.

One of the first drawbacks encountered when the internal combustion engine had passed the limit of small units readily started by hand, was the problem of getting it under way. The means employed during the fifteen or twenty years that engines sufficiently large to require it have been built, have been numerous and diverse, though long before the end of that period they had reached a common basis in the majority of instances. Some of the earliest took the form of ordinary black powder cartridges, fired by pulling a lanyard as was done on old-time guns, while others were merely small motors of the same type, which were started by hand and their power utilized to turn over the larger engine until it took up its own cycle of operation. Still another that is in use to-day on comparatively small motors consists of a hand-pump by means of which an explosive mixture may be forced into the cylinder under compression.

The latter also dates back a number of years, and it has come to be the commonly accepted type, except that the engine itself is depended upon to generate the compression and air alone under pressure is stored in a tank. This is utilized either by direct admission, operating the motor as a single-acting air-engine until it takes up its cycle, or through the medium of a small compressed-air motor. In view of the general acceptance that this manner of starting large power-units has met, it seems more than strange that there should have been any hesitation in its adoption on the automobile. That the ability to start the motor from the seat has long constituted something greatly to be desired goes without saying, but that there has been, during the past few years, a somewhat inexplicable groping further afield, resulting in more or less abortive complication, is likewise true. It has been responsible for the numerous devices that have come and gone

without the car being any the better as the result of their invention. A self-starting device to be successful must, above all, be simple and easily controlled, and, barring the use of a lever at the seat, which is merely the handcrank in another place, compressed air seems to fulfill these requirements better than anything that has been tried thus far.

Influence of the Automobile on Motor Design. It has been well said that the changed requirements of automobile service have brought about the evolution of a motor that differs almost as much from its predecessor, the internal combustion motor of the stationary type, as the latter does from the steam engine. But a comparatively few years ago the prediction that such a motor, as is now in common use on the automobile, could be produced, would have been ridiculed. Including its bedplate, a modern gasoline engine of the stationary type rated at but 6 horsepower, weighs from 1,100 to 1,500 pounds. Assuming that the bedplate accounts for at least 50 per cent. of this, it may still be said that engines of this type will average close to 100 pounds per horsepower. It is evident that not alone this, but half of it, would be an excessive unit of weight per horsepower for the automobile, and though, ten years ago, the stationary engine designer would have ridiculed a motor that weighed not more than 10 to 12 pounds per horsepower, as nothing more substantial than an inventor's dream, this has come to pass and a still greater reduction is being sought for.

A new influence is at work to make a motor in which the weight bears an even more remarkable ratio to the power output, not only a possibility but a practical reality. This is the demand for a motor suited to the requirements of aerial navigation. In brief, these are merely that the motor shall produce the greatest power with the least weight, and though in passing through the throes of invention such as assailed the automobile builder several years ago, designers of aerial motors have brought forth some truly wondrous creations, they have also achieved some very remarkable results. Every expedient known to the designer has been resorted to in order to increase the power and reduce the weight, and such figures as three or four pounds to the horsepower have been attained. This naturally represents a standard considerably below the safe practical limits—in fact, it has not been found practical to design a motor having less than six pounds per horsepower. But whether above or below this limit, the chief stumbling block that the designer of motors for aerial purposes has had to contend with is the factor of reliability. It has been found possible to build motors of these seemingly impossible weights and motors that would run—but their operation has been fitful and uncertain. Still there appears to be no reason to doubt that eventually success will reward efforts in this direction as it has in the case of the automobile.

Is Revenue the Sole Object of Auto Laws?

Legislation that will bring about perfect regulation of any activity, that will be just and, above all, that will equitably affect the interests of all concerned, can never be enacted at the behest of any one branch of the community. The radical would banish the automobile from the highway totally; his less prejudiced co-worker would permit its continued existence under practically prohibitive restrictions and so down through varying degrees of severity. The New Jersey statute, which is being hailed as a success by its advocates after six months' trial, is a typical instance of the result of legislation enacted to benefit one section of the community at the expense of another. In its formulation, both equity and comity were equally ignored and its alleged success consists largely, if not entirely, in its efficacy as a revenue producer. Of the fact that its instigators have succeeded in mulcting the same number of autoists of a larger sum than ever before, there can be no doubt, but a long step backward was taken where equitable legislation on the subject is concerned.

WYCKOFF, CHURCH & PARTRIDGE DINNER.

A notable galaxy of automobile stars sat at the speaker's table at the annual dinner of Wyckoff, Church & Partridge, held on the evening of December 27, at Reisenweber's, New York City. It has been the yearly custom of this up-to-date concern to have a dinner, and this time the intent was to make it of a character representative of the entire industry, and the effort was unquestionably successful. Job E. Hedges, the legal luminary of the American Motor Car Manufacturers' Association; Charles T. Terry, counsel for the National Association of Automobile Manufacturers; M. I. Brock, associate manager of the Association of Licensed Automobile Manufacturers; Senator Martin Saxe, well known in automobile legislation; Senator Slater; A. R. Pardington, manager of the Long Island Motor Parkway; S. M. Butler, secretary of the Automobile Club of America; Dr. F. A. Cook, a noted Arctic explorer, whose next effort will be to the South Pole, and the Rev. Arthur Whittenham, of Oxford, were those who supplied speeches, humorous, interesting and instructive. After C. F. Wyckoff had made a well-worded address of welcome, he turned the oratorical feature over to Toastmaster Thomas F. Moore.

Mr. Hedges, among other things, stated that the sentiment against automobiles as such is dying out. Senator Saxe commented that judges were needed rather than additional legislation for the enforcement of the present laws. Mr. Terry predicted that some day the only legislation necessary will be such as to provide for complete identity of machines and the exercise of due caution in the use of the highways. Over a hundred were present at the function.

AUTOMOBILE MAIL SERVICE FOR MILWAUKEE.

Postmaster Owen, of Milwaukee, has let it be known that on and after February 1, 1907, the "beer city's" mail is to be collected with the aid of automobiles. Three machines have been ordered for the service and it is confidently expected that they will be ready to go into commission on that date. The city has been divided into districts so that both the business and the outlying districts will be better served than by the old methods.

FOUR MILES MORE FOR THE PARKWAY,

Though it is reported that some of the landowners along the route of the proposed Long Island Motor Parkway are holding out for big prices, this is not the case generally by any means. A. R. Pardington, the manager of the Parkway, is just in receipt of the following letter from W. H. Jones, chairman of the board of supervisors of Nassau county, which speaks for itself:

"I have authority to offer you about four miles of right of way east of Hicksville, through lands which I own and two of my neighbors. One of my neighbors is, at the present time, in Paris. I wrote to her some time ago and she has authorized me to offer this to the Parkway company. I have taken up the matter with some of our people who own property nearby, and all of them will, I think, donate the necessary right of way. I have other parties who are interesting themselves and will probably report to you very shortly."

AN INTERESTING DECISION IN TANK CASE,

After hearing arguments on the petition of the Avery Portable Lighting Company, to restrain the Commercial Acetylene Company, Indianapolis, Ind., who are plaintiffs in the patent infringement action brought against the former concern in July last, from continuing to institute actions against buyers of the Avery apparatus, Judge Quarles, sitting in the U. S. Circuit Court of Milwaukee, Wis., rendered a decision prohibiting the plaintiff from bringing further suits against the customers of the Avery company until the validity of the patent had been passed upon.

WORK BEGUN ON MAXWELL-BRISCOE PLANT.

NEWCASTLE, IND., Dec. 29.—Work on the foundation of the new plant of the Maxwell-Briscoe Company is already under way here, the contract, which was formally awarded a few days ago, calling for the completion of the foundation within 60 days from date. It was let to Gubbins & Garvey, a local firm, and involves a total of about 1,200 cubic yards of concrete construction. Bidding for the work was brisk, a number of outside firms also submitting estimates.

HOW THE DINERS LOOKED WHEN CAUGHT BY THE CAMERA AT THE WYCKOFF, CHURCH & PARTRIDGE ANNUAL SPREAD.

SELDEN COMPANY BEGINS BUSINESS.

ROCHESTER, Dec. 31.—The Selden Motor Vehicle Company, which was incorporated December 24 with \$500,000 capital, called the first meeting of its stockholders late last week. The principal business of the meeting was the election of officers, those chosen being George B. Selden, president; L. A. Fischer and J. M. Walmsley, vice-presidents; Gilbert E. Mosher, treasurer, and R. H. Salmons, secretary. With the exception of L. A. Fischer, who hails from Buffalo, all of the officers are residents of Rochester. The directorate of the company will be composed of the above mentioned officers, besides George E. Foster, of the Foster-Armstrong Company, Frank A. Russell, of Rochester, and A. Snyder and A. G. Bartholomew, of Buffalo. Mr. Russell will be superintendent of the factory.

The manufacturing plant of the company will be at East Rochester, N. Y., where operations have already commenced for the erection of buildings covering over eight acres of ground. E. T. Birdsell, formerly connected with the Napier Company abroad, and who has been with the Decauville interests since coming to this country, will be the company's designer, and it said that he has been at work on the plans of a car for some time past in New York. He will continue the work from now on in the temporary offices opened in the German Insurance Building in Rochester. It is planned to place but a single model on the market during the coming year, though the company will also build a runabout later on. This first model will be a touring car listing in the neighborhood of \$4,500 to \$5,000, and no efforts will be spared to make of it as high-grade a vehicle as can possibly be turned out. Commercial vehicles will also be added to the factory's output in the course of time. The first car of the touring type to which the company expects to confine itself during the coming season is expected to be ready about June 1.

A license has been granted the company by the Association of Licensed Automobile Manufacturers, controlling the Selden patent, though for a time the spectacle was presented of an inventor unable to manufacture under his own patent. This arose out of the rule of the association that no license shall be granted until the applicant therefor has demonstrated its ability to manufacture automobiles of the standard required and has actually sold some of them. The license was first applied for a year ago, when the company was being promoted, but was then refused owing to inability to comply with these requirements. The license acquired was that formerly held by the Buffalo Gasoline Motor Co.

Though no details of the car to be built have been made public, it is said that its chief characteristic, so far as the motor is concerned, is that it will be equipped with a device providing an absolute safeguard against backfiring. This is the invention of George B. Selden, Jr. It seems that there have been numerous accidents from this cause in Rochester, one of them having ended fatally, which led to the invention of the device in question.

HYATT FIFTH "ANNUAL" AT THE WALDORF.

In anticipation of its "Fifth Frictionless Feast," which will be held during show week, January 12-19, or to be more exact, on Wednesday, January 16, in the Astor Gallery at the Waldorf-Astoria, Peter Severin Steenstrup, of the Hyatt Roller Bearing Company, who is chairman of the "Feast" committee, has sent out a neat little pamphlet recalling to mind the "Hyatt Idea" and abjuring the recipients to forego other engagements on that evening. Instead of the usual formal gorging with the prepared-in-advance "extemporaneous" speeches as a windup, there will be a continuous service of refreshments, solids and otherwise, from 9.30 P.M. to midnight, helped down by a continuous performance from 10 P.M. to 1 A.M.

Director Willy Tischbein of the Continental Caoutchouc & Rubber Company, Hanover, has received the Order of the Crown Class IV, from the German Emperor.

THE INCREASING GARAGE LIST.

The "Hub" to Have Another Motor Mart.

The New England Electric Cab Company, which now has its headquarters at the Park Square automobile station, is preparing to give Boston another mammoth garage somewhat similar in plan to the now well-known Motor Mart on Columbus avenue. Preparations have been made so quietly that the building was already in the course of construction before anything concerning it became public. It is situated in the Back Bay district, on Huntington avenue, directly adjoining Chickering hall. When completed this new garage will have three stories and basement, each containing 10,000 square feet of floor space. The basement will contain the washing department and machine shop, while a second set of washing machines will be installed on the first floor. Executive offices and chauffeurs' rooms will occupy the second floor, and storage for cars the third. The entrance will be in the center of the building and will be flanked by two large salesrooms. The enterprise is to be known as the Back Bay Motordrome, and will be under the management of W. H. Taylor, who was with the Park Square station for four years.

Copley Square Garage is Boston's Latest.

Boston is to have another motor mart, to be called the Copley Square Garage, and it is to be erected on the site of the old studio building on Irvington street, in the Back Bay, near Mechanics building. Work has already begun in clearing away the old structure to make way for the new garage. It is intended by the builders to make this a combination garage, sales headquarters and clubhouse. Suitable quarters for salesrooms are lacking in this city and as each new firm arrives on the scene it has increasing difficulty in finding a good site for a salesroom. It may be that the Copley Square garage will become headquarters for the unlicensed dealers. Negotiations have been made in an unofficial way looking toward the use of a part of the garage by the Bay State Automobile Association. The association is very well satisfied where it is, however, and as it has a long lease on its present clubhouse would probably decline to move, unless it would be materially benefited.

Detroit's Latest Modern Garage.

Although Detroit boasts of an automobile "row," the same as other cities, the garage business is not confined to it. Beyster & Thorpe, a partnership recently organized with \$25,000 capital to do a garage business, has erected a garage and salesroom way out in the best part of Detroit's residential district, 1329-1331 Woodward avenue, only a few blocks from the fifteen-mile Grand Boulevard. The building has a fifty-foot front, most of which is of plate glass, and has a depth of 100 feet. Every facility for the rapid and convenient handling of cars has been provided, the plan of the building being modern in every detail. The selling end will be confined to representing the Aerocar, and a large electric sign of the latter will be placed across the entire front of the garage later. The front and main entrance is shown in the illustration.

MAIN ENTRANCE BEYSTER & THORPE GARAGE, DETROIT.

COMPRESSED AIR FOR SELF-STARTING DEVICES

By CHARLES B. HAYWARD

EVER since the automobile reached a stage of development where its designer was at liberty to feel that the chief question of moment had ceased to be "will it run?" the necessity of some simple device to enable the driver to start the motor from the seat has made itself more and more apparent. Whether considered casually or closely investigated at close range, the problem is not one that should hold any particular difficulty. Power must be applied to turn the motor over until it takes up its own cycle, and this power may take any form that the designer considers simplest and most adaptable to the purpose. The only other essentials are that it shall be easily controlled from the seat and readily detachable from the motor shaft when the latter starts.

Ever since gas engines of high powers have been built, and they date back some time before the modern automobile, compressed air has been relied upon in the great majority of instances to get the engine under way. In one or two instances, such as that of the large multicylindered stationary engine built by the Wolseley Works for the General Electric Company, a cartridge containing gun powder is inserted in a breech provided for it and fired by pulling a lanyard—altogether a crude and antiquated device, as well as one totally unsuited for the purpose where frequent starting is necessary. Its use dates back a number of years; but, in the more or less infrequent instances in which it has been employed, it has had to give way to compressed air or something similar sooner or later.

For starting an automobile three classes of devices seem to lend themselves most readily to the end in view. A hand lever operated from the seat, turning the motor over by human power in much the same way as is done with the crank at present; spring devices wound by the motor, and gas or air under compression, also maintained at the required pressure by the motor, though in some instances an independent reservoir has been utilized. It is evident that of all these the use of compressed air promises most, on the score of simplicity and reliability, next to the hand lever at the seat, which is merely the crank in another place. A form of starting large engines that has not been mentioned is that of employing a smaller motor of the same type to turn over the large one, but as this must be gotten under way in the usual manner, it has no bearing

on the problem whatever. Then, again, comparatively small engines of the stationary type have been on the market for years, in which self-starting is accomplished with compressed air generated by means of a hand pump, but this also is objectionable, beside which there is no necessity for resorting to hand power to generate the pressure in the case of the automobile motor. The muscular effort might better be expended directly at the crank handle.

HOW THE PUMP IS ATTACHED TO THE MOTOR.

However it may be viewed, the problem inevitably seems to point to the use of gas or air under compression, the only question of moment being whether to inject it directly into the cylinder or employ it in the form of an auxiliary motor. The latter appears to represent the simplest form, a typical instance of this being found in the device employed on the Renault cars. This concern adopted compressed air for self-starting last year, but the device has been considerably improved in the interim. In place of the small three-cylinder compressed air motor used formerly, two single-acting cylinders facing one another and with their pistons acting on racks, between which a ratchet pinion attached to the end of the motor shaft is placed, have been substituted. The pump is gear-driven from the motor and supplies a tank that may be placed wherever most convenient on the chassis. A pressure of 12 kilograms per square centimeter is automatically maintained in this tank by

SECTIONAL ELEVATION SHOWING CONNECTIONS OF COMPLETE SELF-STARTING PLANT.

means of the pump and a diaphragm valve, permitting the escape of any excess. The method of operation is as follows: The lever *F* at the end of the camshaft (Fig. 1) drives the piston *P* through a connecting rod. The air intake is at *L*, while the compressed air reaches the tank through the valves *K* and *O* and the tube *N*. A needle valve *Q* is provided on the tank, and, when closed, maintains a supply of compressed air in the latter. The tank has a cubic capacity of six liters, which, at the pressure maintained, permits of starting the car six times in succession before exhausting it. The valve *Q* is allowed to remain open, except when the car is out of use.

In order to start, a pedal on the footboard is depressed, opening the valve *T* and allowing the compressed air to flow into the cylinders, thus forcing the pistons *E* and *D* outward. The two horizontal racks act on the pinion attached to the crankshaft of the motor. Having completed their stroke the cylinders are emptied by the rack *M*, which is hollow for a portion of its length, engaging the connecting rod *I* and tripping the lever *J*, which opens the valve *X* and empties the cylinders automatically, when the operation may be repeated by depressing the pedal again.

NEW DELIVERY AUTO OF THE BROOKLYN "DAILY EAGLE."

CREATING A LIGHT DELIVERY CAR.

There has been recently added to the automobile delivery force of the Brooklyn *Daily Eagle* a car which that enterprising journal recommends as a type especially suited for quick and effective work, where attractiveness in appearance is not to be lost sight of. The new creation consists of a regular Pope-Toledo chassis on which a special seat and body has been built by Flandreau. The illustration shows a very happy combination, which its users are extremely well pleased with after a practical test.

FREE REPAIRS FOR A YEAR ON 1907 CARS.

Many a would-be automobilist has undoubtedly been prevented from buying a car because of the haunting fear that the trouble and expense of keeping it in running order would be so great as to offset the pleasure derived from the use of the machine. Not very long ago there was very good reason for such fear; but the great improvements made in late years have made well-built cars exceedingly reliable. A striking indication of this fact is given in the statement made by the Quaker City Automobile Company, of Philadelphia, that 1907 cars bought from it will be kept in repair free of charge for a year, and each purchaser of a 1907 car is given a signed contract to this effect. This does not apply, of course, to damage caused by accident. The cars handled by this concern are the Pope-Toledo, Pope-Hartford, Pope-Waverly, Pope-Tribune, Franklin and Peerless, and the company's confidence in their quality is strikingly indicated by the free repair offer.

DIAMOND RUBBER CO.'S CAR FOR PRACTICAL DEMONSTRATIONS.

A PRACTICAL TIRE TRY-OUT TRIP.

AKRON, O., Dec. 31.—As a means of presenting by practical performance the merits of the Marsh Rim and Diamond Quick Detachable Tire the Diamond Rubber Co. has put a car on the road expressly for this purpose. Notwithstanding severe weather and bad roads, the Diamond demonstrators have made rapid progress from place to place, and the health-giving qualities of automobiling, even in winter, are evidenced by the fact that the men have gained perceptibly in weight in a very short period. The record of the Marsh rims on this car has been gratifying to the Diamond company.

WASHINGTON'S PROSPEROUS YEAR'S TRADE.

WASHINGTON, D. C., Dec. 29.—Prosperity and general trade expansion have been the distinguishing features of the automobile trade in this city during the year just closing. It can be truthfully said that this statement is an accurate description of the local trade during the year. Whatever is said beyond this is merely elaboration. Everybody has been unusually prosperous and will close the year with substantial balances on the right side of the ledger. It is estimated that fully 500 automobiles of all descriptions were sold here during the year. Electrics have made great headway during the year.

The Commercial Automobile and Supply Company has removed from 715 Thirteenth street to 1313 New York avenue, a large three-story building that was remodeled for the use of the company. Wayne and Logan cars will continue to be handled.

The work of remodeling the building at 1315 New York avenue for the Motor Car Company, agents for the Peerless, Thomas and Stevens-Duryea, is progressing rapidly.

A QUAKER CITY SIGN THAT TELLS ITS OWN STORY

NEWS AND TRADE MISCELLANY.

Following the annual custom of playing Santa Claus, Harry Houpt, the New York Thomas representative, distributed among his two hundred employees and the chauffeurs who store their cars in his garage, a ton of turkeys as Christmas presents.

Owing to the great increase in its business, the Auto Brass Company, Columbus, O., makers of lamps and accessories, intends to build a plant of its own during the coming season. George Hill is the president and M. B. Lee the general manager.

Raymond S. Joo, whose Frayer-Miller car came out victorious in the recent endurance test that started off as an economy run, and who represents the Frayer-Miller interests in northern New Jersey, has just removed to a new garage at 79 Orange street, Newark.

The Cornish-Friedberg Automobile Company, representing the Aerocar and other lines in Chicago, has just moved into a specially constructed garage building at 1233 Michigan avenue. It is two stories high and is one of the most complete establishments on the row.

Charles Howard Tucker, formerly manager of the Chicago branch of the Wintou Motor Carriage Company, is the designer of the new Chicago production, the Triumph car. The company building it expects to be able to have at least 100 touring cars on the road during the coming season.

The Autocar Company has just leased the premises consisting of the corner store and basement at Eightieth street and Broadway for a term of years. The building is a new one, and as soon as the necessary fittings can be installed the New York branch of the Autocar Company will occupy its new location.

The Auto Vehicle Company, of Los Angeles, Cal., will expand to a considerable extent on the completion of its three-story brick structure to be erected at the corner of Tenth and Los Angeles streets, the contract for which has just been awarded. The factory of the company is now situated at Tenth and Main streets.

The recently incorporated Star Automobile Company, of Chicago, which will manufacture light gasoline runabouts, is looking about for a favorable location for its factory. Marion, Ind., on the other hand, would welcome a further increase in its automobile manufacturers, and it is probable that this city may be selected.

George H. Earle, Jr., president of the Real Estate Trust Company, of Philadelphia, one of the Quaker City's veteran automobilists, has placed his order for a 1907 Autocar. Mr. Earle has owned every type of Autocar that has been built, and although he owns a number of foreign machines, is very loyal to the production of the Ardmore factory.

The eight cars of the new Pope-Toledo Livery Company, which has its headquarters in the Orlando F. Weber garage, at 1322 Michigan avenue, Chicago, have been kept busy ever since the company started in business about ten days ago. The officers of the company are Charles Weber, president; Alfred Reeke, secretary-treasurer, and Harry Griffin, manager. Five of the cars are of the open touring type and the other three are well fitted limousines.

The Maxwell-Briscoe Motor Company, of Tarrytown, N. Y., has purchased the entire edition of "The Making of an Automobilist" and is selling the book almost at cost, the price asked being 50 cents. The

idea is that users of Maxwell or any other cars can learn a great deal about the handling and care of their machines from this practical book, and that its distribution in this way will be of benefit to the automobile movement generally.

Oakland, Cal., has purchased for the use of Chief Ball, of the fire department, a Columbia 24-28 horsepower runabout. The chief insisted on being "shown" what the car possessed in the way of staying qualities, hill-climbing ability, speed, etc., and the sale was made by the Middleton Motor Car Company, Pacific Coast representatives of the Electric Vehicle Company, who recently secured the order from the city of Oakland for a Columbia electric police patrol.

At a meeting of the directors of the recently incorporated Shoemaker Automobile Company, of Freeport, Ill., it was decided to increase the capital stock of the concern to \$100,000, divided into 4,000 shares at \$25 each. Although one of the objects set forth in the incorporation papers is that of manufacturing automobiles, it is expected that the company will confine itself to do a general selling and garage business. A building on Exchange street has been leased.

✓ The Welch Motor Car Company has just awarded a contract to the Slater Construction Company for the erection of a building for manufacturing purposes in Pontiac, Mich. The new factory will measure 100 by 250 feet and will be modern in every detail. The contract calls for its completion at the end of sixty days and as soon as ready new machinery will be installed in it, tripling the capacity of the Welch company to turn out cars. Its present plant has been running night and day.

Just to show what field there is for automobiles, the American Motor Car Association has just issued some of the records of the Census of Manufacturers for 1905, which show that during that year 6,000 carriage and wagon builders in this country turned out 1,700,000 horse-drawn vehicles, valued at \$97,000,000. Family and pleasure carriages numbered 940,000, valued at \$57,000,000, while business and farm wagons were made to the number of 644,000, worth \$37,000,000. There were 127,000 sleighs made.

James M. Mills, who represents the Cadillac interests in and about Newark, O., recently extended an invitation to every one of the owners of that make of car in that enterprising city to attend a dinner in honor of the success of the car during the past year. There are 55 Cadillac owners in Newark, and each was invited to come and bring a guest. The dinner was preceded by a theater party and followed by a recital of their experiences on the part of the guests. The affair was well attended and proved most enjoyable.

The successful Grand Central Palace show, and unusual activity of the American Motor Car Manufacturers' Association, has tended to increase the interest in its affairs which is resulting in added membership strength. A number of applications are now in the hands of the membership committee and last week two concerns were elected to the roll, which now numbers 41 manufacturers of motor cars. The two new members are the Abendroth & Root Manufacturing Company, makers of the Frontenac, and the York Motor Car Company, of York, Pa., makers of the Pullman.

Recent amendments to the constitution of the American Automobile Association have been drafted with a view to benefiting autoists who are not attached to any other organization. In accordance with the new regulations, any one now taking out an individual membership, the cost of which is still \$2 per annum, will not only receive the usual benefits but his name will also be sent to the state organization where he resides. This, together with the new ruling that henceforth any one hundred members of the national body may combine to organize a state association where at present there is none, should prove an incentive that will bring about a large increase in the membership of the association.

The Knox Automobile Company, of Springfield, Mass., one of whose cars is used in that city by the fire department for carrying chemical apparatus, tools and men rapidly to fires, has arranged with the Combination Ladder Company, of Providence, R. I., large manufacturers of chemical fire extinguishers, to place on the market a stock model of this fire-fighting automobile. The machine will consist of a Model G chassis with four-cylinder 35-40-horsepower motor, carrying two 35-gallon chemical tanks, the paraphernalia usually carried by such wagons and the men necessary to properly handle the apparatus. The first model of this interesting machine will be exhibited at the Madison Square Garden show, in the commercial vehicle section.

NEW AGENCIES ESTABLISHED.

The agency for the Dragon car for Minnesota's Twin Cities and vicinity has been placed with the Auto Selling and Repair Company, of Minneapolis.

The Pacific Commercial Car Company has been organized at Seattle, Wash., with a capital stock of \$25,000, and will handle the Cartercar. The incorporators are E. R. Wheeler, L. E. Younnie and Albert Armstrong, all of Tacoma, Wash. Salesrooms and garages will be maintained in both Seattle and Tacoma.

E. E. Cole, for several years connected with the Boston branch of the Wintou Motor Carriage Company, has gone with the Franklin interests in that city. The latter concern expects to occupy its new quarters, at 671-673 Boylston street, about the first of the year. The new salesroom is directly opposite the Public Library.

The Autocar Company, of Ardmore, Pa., has this week closed contracts for 1907 with the following dealers: Youngs & Co., Newburgh, N. Y.; Frank P. Freeman, Rahway, N. J.; the Auto Company, Paterson, N. J.; August Stocker, Salt Lake City; the Cook Automobile Company, Portland, Ore., and the Broadway Auto Co., Seattle, Wash.

Wishing to extend their business into the Dominion, which is known to represent an excellent field for high-grade cars, the F. B. Stearns Company, Cleveland, O., makers of the Stearns cars, are desirous of getting in touch with responsible dealers in various parts of Canada, especially in such cities as Toronto and Montreal, in order to establish agencies for the coming year.

The Northwestern Cadillac Company has been formed to handle the Cadillac line in Minnesota, North and South Dakota, with headquarters in Minneapolis. They have opened a garage at 316-322 Fourth avenue, south, where a complete stock of supplies and parts will be carried and a general repair business conducted. The Waverley electric line will be handled for the city of Minneapolis. L. E. Horton is manager of the new company.

PERSONAL TRADE MENTION.

W. E. Decker, lately with the Maxwell-Briscoe Buffalo Company, has been transferred to the selling department of the Maxwell-Briscoe Co., Inc., New York.

P. A. Williams, who was manager of one of the departments of the Overman Wheel Company in the old bicycle days, and has since been connected with the automobile industry as representative of the Orient, Ford and Marion lines in Boston since 1903, later going with the Aerocar Company, has just been appointed sales agent of the runabout department of the Knox Motor Truck Company, of Springfield, Mass. The car is the Atlas, two cylinder, two-cycle runabout of 20 horsepower, which was in evidence at the recent show, together with the heavy two-cycle commercial vehicle staged by the same firm.

AN ADJUSTABLE BAGGAGE RACK.

Adjustability to every size of car, great or small, is the leading feature of the new baggage rack just placed upon the market by Pedrick & Smith, Church lane, Germantown, Philadelphia, an illustration of which is printed below. It is made of pressed steel throughout and is attached to the back of the seats by brackets. Both the

P. & S. ADJUSTABLE BAGGAGE RACK.

main framework, on which the baggage rests, and the two side supports, are adjustable as to length, this feature being the prime requisite in fitting it to the various sizes of cars. The rack, with its load, is carried well above the deck, so that this can be removed for inspecting the mechanism of the car without disturbing the baggage. When there is nothing to be carried, the rack folds up against the back of the seat and is entirely out of the way, yet ready for instant use. The rack is made in sizes suitable for all standard cars, and its length can be adjusted to suit individual requirements by means of the sliding arrangement in the main frame members. The P. & S. baggage racks are finished in black enamel and are exceedingly strong and durable.

TWO HAYES NOVELTIES.

An auto that does not drop oil on the floor of the garage is a rare thing, and to the man who has a private garage and likes to keep it clean this is a sore point. For just such service the Hayes Manufacturing Company, of Detroit, Mich., has placed on the market a floor pan of heavy galvanized iron, 30 inches wide and 94 inches long; angle iron stiffening strips are riveted to the bottom and casters are provided to make moving it about an easy matter. Besides the regular size mentioned, special sizes are made.

The same concern is turning out metal boxes for batteries and for tools. The

front, back, and bottom of each box are made from a single piece and the ends are set in and double seamed. The cover has wired edges and the edges of the body are also wired. Brass hinges, locks, hasps, and staples are fitted, or else there is a brass loop on the cover through which a strap may be passed. The standard size is 8 1-2 inches wide, 10 inches high, and 16 1-2 inches long. When used for a battery box a light wood lining is put in. Two storage batteries can be carried in one box, or else one storage battery and one set of dry cells. The finish is black enamel, baked on at a high temperature. Special sizes are made to order.

GISHOLT'S AMERICAN LATHE.

In these days of high-speed methods machine tools must be made to take heavy cuts without springing or chattering, for otherwise the finished work will lack accuracy and the best speed cannot be realized in its production. The accompanying illustration shows a good example of a heavy special lathe manufactured for the Gisholt Machine Company, of Madison, Wis., by the J. Morton Poole Company, of Wilmington, Del. The lathe is of the semi-automatic turret type, and is made with and without the gap bed. The manufacturers state that it is particularly adapted to machining flywheels, and that it is used in a number of automobile manufacturing establishments.

The massive construction of the machine is at once apparent. The bed is of very deep section and the headstock is cast integral with it, the maximum stiffness being thus obtained. The spindle is of large diameter and is ground absolutely true on dead centers; it is bored with a 2 3-8-inch hole and runs in heavy bronze bearings arranged with concentric adjustment for wear so that when such adjustment is made the spindle will not be thrown out of alignment. Four ratios of double back gear are provided in the driving gearing, as well as two ratios of quadruple back gear; with the two-speed countershaft this gives no less than thirty-six spindle speeds. There are eight feed rates, varying from two to thirty-five cuts to the inch. The driving belt is four inches wide. The turret is large and heavy and affords a wide base to steady the tools in taking heavy cuts. On the standard machine, which has a swing of 24-27 inches, the turret is 35 inches in diameter across flats; the turret faces are 8 inches high. The turret

has a traverse of 54 inches. The chuck is 24 inches in diameter. The swing over the turret slide is 8 inches. The American lathe is also made with 24-27-inch swing, this size having no gap. The weight of the machine is about 8,700 pounds.

RECENT INCORPORATIONS.

H. S. Hout Company, New York; capital, \$300,000. Incorporators, E. M. Hout, F. J. Titus and A. S. Robinson.

The American Motor Company, Eau Claire; capital, \$15,000. Incorporators, C. T. Bundy, Roy P. Wilcox, and Hannah F. Johnson.

Jackson Motor Car Company, Brooklyn, New York; capital, \$20,000. Directors, C. M. Herring, H. W. Palmer and F. H. Palmer.

Pope-Toledo Automobile Livery, Chicago, Ill.; capital, \$5,000. To deal in automobiles and supplies. Incorporators, Alfred Reeke, Harry G. Griffin and Charles Weber.

Model Machine Works, Frankfort, Ind.; to manufacture and repair automobiles; capital stock, \$10,000. Incorporators, Jos. Palmer, Chalmer H. Hillis and Andrew A. Laird.

Cincinnati Motor Car Dealers' Company, Cincinnati, O.; capital, \$5,000. Incorporators, Joseph T. Monfort, Charles Hanauer, Sid Black, Robert C. Crowthers and James H. Ratcliffe.

Halfeld Motor Vehicle Company, Scranton, Pa.; capital, \$50,000. To manufacture motor and self-propelled vehicles. Incorporators, C. B. Halfeld, C. B. Halfeld, Jr., Cortland; C. H. Pond, Scranton, Pa.

The Allegheny Motor Vehicle Company, Trenton, N. J.; capital, \$50,000. To manufacture and deal generally in automobiles. Incorporators, E. L. Kerns, W. Harry Williams and Walter G. Reinman.

Baird-Banks Manufacturing and Supply Company, New York; to manufacture and deal in automobile and motor boat supplies; capital, \$25,000. Incorporators, Milan E. Baird, George E. Banks and William James.

The Electrical Switch Plate Company, Hartford, Conn.; capital stock, \$50,000. To manufacture and sell switch plate. Incorporators, John Alexander, William H. Miller, Daniel H. Judd and Francis H. Peabody, of Hartford, and Oscar E. Joss, of New Haven.

Dealers' Automobile Exchange and Development Company, Rahway, New Jersey; capital stock, \$125,000. To buy, sell and deal in automobiles. Incorporators, Charles W. Nichols and Samuel D. Mershon, Rahway; and Herbert W. Walker, New York.

SEMI-AUTOMATIC TURRET LATHE, MADE BY THE GISHOLT MACHINE COMPANY.

THE AUTOMOBILE

VOL. XVI.

NEW YORK—THURSDAY, JANUARY 10, 1907—CHICAGO

No. 2

MADISON SQUARE GARDEN'S SEVENTH SHOW

NOW the annual automobile show in Madison Square Garden. This world-known structure has been the scene of many events, but the 1907 affair of the Licensed Association of Automobile Manufacturers will set a new standard for the only well arranged structure possessed by the metropolis of the country—a building utterly inadequate to meet the astonishing demands of an industry that in the short space of six years requires two national shows in New York City in order to present its product, and even then twice as much display space could be utilized were it obtainable. The "Garden Show" embraces the pioneers, with few exceptions, and the present trend of American practise finds more general expression in the Selden camp than could be expected from any body which included many newcomers in automobile manufacture. Two hundred and sixty-five separate exhibits will be the Garden total, including the cars of the members of the Association of Licensed Automobile Manufacturers, the importations of the Importers' Automobile Salon and the quiet-running productions of the Association of Electric Vehicle Makers, and, in addition, the diversified showings of the firms belonging to the Motor and Accessory Manufacturers, Inc. Never before has the Garden show been so thoroughly departmentized. On the main floor and elevated platforms there will be the gasoline, domestic and foreign, pleasure cars; in the café the electrics will repose, and down

in the basement the ponderous commercial carriers and some of the overflow accessories will be found. Incidentally it might be mentioned that a rathskeller at the Fourth avenue end will provide a gathering place for those socially inclined. The greater part of the accessory and sundry concerns will be distributed through the concert hall, on the mezzanine platform, and in the gallery. Never has the Garden been subjected to such a thorough rejuvenation; it simply will not be recognized by its patrons of many years' standing. The Publicity Department described the decorative scheme as resembling "a Swiss palace in Autumn"—exactly what that might be is something of a mystery. Nevertheless, the transformation has been artistically accomplished, and one is easily inclined to utilize gorgeous adjectives in telling of the beauty of the place. Snowy peaks, tawny fields and amber skies are depicted in the huge paintings at the end and sides, while heroic statues and fountains add to the general effect with its Alpine complexion. 'Tis said that \$75,000 has been expended in supplying the garb of the Garden, which certainly presents a harmonious and symmetrical plan of decoration, with its uniform signs and lights. Certainly the "Goddess of the Show" and her sisters gaze upon a scene unlike that which ever before has served as a setting for an industrial entertainment. "Prosperity," "Triumph" and "Mercury" are typical figures which would seem to belong in the capacious amphitheater.

SOME OF THE SHOW GIRLS

Nearly 150 different models will be presented, ranging from the costliest down to the reasonable little run-about; they will be water-cooled and air-cooled; of eight, six, four and two cylinders; in limousine, landaulet, touring car and run-about form; in fact, the man who cannot be suited will certainly be difficult to please, and the captious will find variations in equipment that will keep him busy for several visits to the big building. Not a nook nor a cranny in the Garden has been left un-

tenanted, but all the occupants are related in one way or another to the commanding auto in its victorious speed march.

Forty-three different makes of gasoline cars will be represented, with eight electrics interspersed and eleven commercial trucks contributed to preserve the equilibrium. The foreign cars will be direct from the Paris Salon, and of course 1907 models beyond question. This is the car list of exhibitors:

AMERICAN GASOLINE.

Apperson,	Locomobile,	Pope-Tribune,
Autocar,	Lozier,	Royal Tourist,
Buick,	Matheson,	Simplex,
Cadillac,	Northern,	Stearns,
Corbin,	Oldsmobile,	Stevens-Duryea,
Columbia,	Packard,	Studebaker,
Elmore,	Peerless,	Thomas,
Franklin,	Pierce Great Arrow	Walter,
Haynes,	Pope-Hartford,	Waltham-Orient,
Hewitt,	Pope-Toledo,	Winton.
Knox,		

FOREIGN GASOLINE.

C. G. V.,	Clément-Bayard,	Hotchkiss,
English Daimler,	Fiat,	De Dietrich,
Panhard,	Rochet-Schneider,	Isotta-Fraschini.
Renault,	Darracq,	

ELECTRIC.

Babcock,	Baker,	Columbia,
Columbus,	Cantono,	Gallia.
Pope-Waverley,	Studebaker,	

COMMERCIAL VEHICLES.

Champion,	Franklin,	Pope,
Knox,	Northern,	Hewitt,
General Vehicle,	Waverley,	Studebaker.
	General Electric.	

GEORGES DUPUY'S EUROPEAN TOUR IDEA.

American manufacturers have been invited to attend a preliminary meeting at which will be discussed Georges Dupuy's "cooperative commercial invasion of Europe by the allied automobile manufacturers of America under the guise of a road and endurance contest for a gold cup." The session will take place at the rooms of the New York Motor Club, Fifty-eighth street and Eighth avenue, January 15, at 11 A. M. Mr. Dupuy outlines a tour that would include France, Spain, Italy, Austria-Hungary, Germany, Belgium and England, occupy about eight or ten weeks, and include at least fifty American cars.

EVENTS SCHEDULED FOR SHOW WEEK.

Sunday, Jan. 13, 8 P. M.—Smoker of New York Motor Club, Reisenweber's, No. 300 West Fifty-eighth street.

Tuesday, Jan. 15, 10:30 A. M.—Monthly meeting Mechanical Branch A. L. A. M., No 7 East Forty-second street.

Wednesday, Jan. 15, 10:30 A. M.—Continuation meeting Mechanical Branch A. L. A. M., No. 7 East Forty-second street.

Wednesday, Jan. 16, 11 A. M.—Annual meeting of National Association of Automobile Manufacturers, Victoria Hotel, Broadway and Twenty-seventh street.

Wednesday, Jan. 16, 9:30 P. M.—Hyatt Roller Bearing Company, "Fifth Frictionless Feast," Astor Gallery, Waldorf-Astoria Hotel.

Thursday, Jan. 17, 2 P. M.—Annual meeting of Society of Automobile Engineers, New Grand Hotel, Broadway and Thirty-first street. Annual dinner, same place, 7:30 P. M.

Thursday, Jan. 17, 3:30 P. M.—Annual meeting of A. A. A. at new A. C. A. clubhouse, No. 249 West Fifty-fourth street.

Friday, Jan. 18, 10:30 A. M.—Meeting of New York State Automobile Association, new A. C. A. clubhouse, No. 249 West Fifty-fourth street.

THE FOUR WHO DID MOST OF THE WORK.

Col. George Pope, chairman of the show committee, has been prominent for years in the bicycle and automobile industry. As treasurer of the Pope Manufacturing Company he had to do with the growth of the motor car industry from its birth and with the promotion of all the shows. He is a man of unusual personal popularity, and his word is taken as a bond throughout the trade. As a presiding officer he has a judicial character which brings discussions to a practical focus.

Marcus I. Brock is one of the forceful men of executive ability. He is the assistant general manager of the Association of Licensed Automobile Manufacturers, in which position he has made himself conspicuous by his handling of heavy responsibilities. Previous to taking his present position he was for a number of years the sales manager of the Autocar Company.

Carleton R. Mabley is of the firm of Smith & Mabley, the first regular importing firm established and now one of the largest importers, besides being manufacturers of an American car. As a close student of the Paris shows, Mr. Mabley brings much valuable knowledge to the conferences of the committee.

Merle L. Downs, secretary of the committee, has been prominent in various ways in the industry and with the work of various organizations. He is known for his work in managing several of the big tours, such as the one to Pittsburg in 1903, and that to St. Louis in 1904, and the Glidden tour of 1905. He is now regularly connected with the A. L. A. M. and most of the burden of detail work in connection with the show falls upon him, as upon secretaries generally.

NAIAD WITH DOLPHIN ON FOUNTAIN.

WHERE THE VARIOUS EXHIBITORS HOLD FORTH

IT is something of a task nowadays to thoroughly "do" an auto show, and the average visitor is first inclined to examine that which appeals to him particularly and then more leisurely wander up and down the aisles, climb to the galleries, and descend to the basement. He may have in mind the buying of a new car, or he may be a pioneer who wants something that is exactly up-to-date, and these are the men who have an object

in mind as soon as they enter the building. Some have a penchant for tires; others want the road well lighted and make for the lamp exhibits; ignition is always a fruitful source of investigation for the old timer, and everyone wants to know how far he has gone and also how fast he is going. Specialties of all kinds add to the grand total, and therefore the accompanying classification will be a great time-saver, as well as a convenience.

GEORGE POPE.

M. I. BROCK.

C. R. MABLEY.

M. L. DOWNS

HOW THE AUTO SHOW IDEA DEVELOPED

By ARTHUR N. JERVIS.

AN argument in favor of January as the time for shows has been advanced recently by no less an important and authoritative person than Col. George Pope, chairman of the show committee of the Association of Licensed Automobile Manufacturers. In his remarks Col. Pope said:

"In years gone by, when the old guard makers were new in the field, and were looking for dealers to handle their product, the national show was largely a trade event, to which the manufacturers went seeking to do business with retailers. Now the old established manufacturers all have their regular line of dealers and the orders from these are booked in the fall. They do not go to the show to engage dealers to handle their output, because they are already supplied in this respect. They go to display their new models to the public, and the show, from being a purely trade event, has become a sort of festival for society and the automobiling class.

"Under these circumstances there is absolutely no call by the well-known manufacturers of the licensed cars for a show before January. They are not firms that started in business last month, or last year, and who have to hunt up dealers to sell their cars. The dealers in licensed cars, like the makers of them, are all established."

This calls attention to a fact of which there can be no question—the character of the Garden show has changed radically within a few years. No longer is it looked upon by the big manufacturers as an annual market for the booking of contracts with agents. This feature of the show has been waning during the last three years, and now the business done at shows between retail dealers and manufacturers is of secondary importance. This change in the function of the show is the more interesting because it is, in a way, a reversion. The first show, like that of this year, was addressed to the public rather than to the trade.

The First American Show in 1900.

A review of the shows brings out the story of the changes and will be interesting at this time. If the exhibition of a few "horseless carriages" at the last bicycle show at Madison Square Garden in January, 1900, be passed over, the first real automobile show was held in the Garden November 3-10, 1900.

Although the credit of the idea has been given to the Automobile Club of America, it really originated with James P. Young, secretary and treasurer of the Madison Square Garden Company. Mr. Young sought the cooperation of the Automobile Club of America, and the first show was announced as being under the auspices of the club.

A good photograph of that show would cause a hearty laugh now, although it was held only a little more than six years ago. There were not enough exhibits to fill the space, even with a board track on the main floor, although motorcycles and motor

tricycles were included with the automobile. The machines themselves were "near automobiles," of the shaftless huggy type, nearly all of them having steam or electricity for motive power. In the café were the nearest approaches to real motor cars. These were loan exhibits of imported cars, owned by members of the club, and they seemed quite wonderful at the time. The track was used for gymkhana events, braking, starting, and stopping tests, and other stunts. The mental attitude of the visitors was similar to that of investigators in an inventor's workshop who call to see if his device is really practical. The presence of the track and the whole arrangement suggested that it was a demonstration to answer the public's skeptical query of: "Will they go?" Very often they would not go. However, the first show was a success financially. During the following week an attempt was made to establish the Grand Central Palace as the home of future shows by inaugurating an exhibition there and announcing it as a continuance of the Garden show. This affair gathered in a few exhibitors who were not ready in time for the other event, but it was only a moderate success, and no attempt has since been made to have a show in that building until the present year.

The complete list of exhibitors at the first show is an interesting one, to glance over at this time, in view of the changes that have occurred. This is the list:

- | | |
|------------------------------------|-------------------------------------|
| Electric Vehicle Co. | Upton Machine Co. |
| Riker Vehicle Co. | Automobile Club of America. |
| Locomotive Co. of America. | Edmond Motorcycle Co. |
| National Automobile & Electric Co. | New York Motor Vehicle Co. |
| De Dion-Bouton Motorette Co. | Munger Vehicle Tire Co. |
| Waitham Manufacturing Co. | Steam Vehicle Co. |
| American Bicycle Co. | Badger Brass Manufacturing Co. |
| Winton Motor Carriage Co. | Bevin Bros. Manufacturing Co. |
| Mobile Co. of America. | E. A. Brecher & Co. |
| Baker Motor Vehicle Co. | Consolidated Rubber Tire Co. |
| Autocar Co. | Crest Manufacturing Co. |
| Foster Automobile Mfg. Co. | Diamond Rubber Co. |
| Automobile Co. of America. | Dixon Crucible Co. |
| Woods Motor Vehicle Co. | Downing & Co. |
| Stanley Manufacturing Co. | Dow Portable Electric Assistant Co. |
| Canda Manufacturing Co. | Geason Peters Air Pump Co. |
| Buffalo Electric Carriage Co. | B. F. Goodrich & Co. |
| Daimler Manufacturing Co. | Goodyear Tire and Rubber Co. |
| Holyoke Automobile Co. | Gray & Davis. |
| Knox Automobile Co. | Hartford Rubber Works Co. |
| Overman Automobile Co. | Janney, Steinmetz & Co. |
| International Motor Carriage Co. | Metallic Rubber Tire Co. |
| Trinity Cycle Manufacturing Co. | Charles E. Miller. |
| John T. Robinson & Co. | New Process Raw Hide Co. |
| Peerless Manufacturing Co. | New York Belting & Packing Co. |
| Springfield Cornice Works. | Pennsylvania Automobile & Gear Co. |
| St. Louis Motor Carriage Co. | C. F. Splittdorf. |
| Haynes-Apperson Co. | Veeder Manufacturing Co. |
| Strong & Rogers. | Ware Bros. |
| Duryea Motor Co. | |

There were no foreign exhibitors in the first show. The Garden was crowded at every session and the show was a success financially, as all succeeding shows have been. The cost of putting the first show on was \$11,000, outside the decorations, which were paid for by the exhibitors.

At this time the manufacturers were few in number and their total output was small. They had little need to look for dealers to handle their output, and it safely may be said that their chief object in participating in a show was that of edifying with the exploitation of new improvements and reviewing enthusiasm in those who were already automobilists, of arousing interest on the part of the public, and of selling cars direct to the users.

Ninety-three in the Second Show.

The second national show was held in Madison Square Garden, December 2-9, 1901. Ninety-three exhibitors took space in this. The track was omitted this time, but again there was a loan exhibit of foreign cars in the café. There was a Mors car shown by Foxhall P. Keene, half a dozen Panhard and Levassor machines, a Darracq, a Napier, a Renault and a Daimler-Cannstatt Mercedes. No foreign exhibitors had space.

The industry had then begun to develop rapidly. There was an increasing output by the factories, so that the makers found it more necessary to act as wholesalers only. The distance between the user and the manufacturer increased and the retailer began to flourish. Thus, during 1902, the show came to be regarded as a wholesale mart of manufacturers seeking to close with dealers. During this year the commercial future of American built cars became more certain. The National Association of Automobile Manufacturers was formed, and after a few conferences it was arranged that the next show should be at the beginning of the year instead of at the close, and that it should be managed by a committee on which the N. A. A. M., the Automobile Club of America and the Garden Company should each be represented, and that each of these organizations should share in the profits. Thus there was no show in 1902, and the third one was held a year and five weeks after the second one, or during January 17-24, 1903. At this show the number of exhibitors totaled 150, and for the first time a foreign firm was an exhibitor; this was the Paris Automobile Co., represented by Henry Fournier.

The Succeeding Shows.

At the third show the horseless buggy type began to disappear in favor of the European type of car, and after this the change of types was rapid, each succeeding year seeing fewer buggies and runabouts, fewer steamers and more gasoline cars. The single-cylinder motor and the horizontally disposed engine also were crowded aside, although not abrogated, any more than were steam and electricity.

The fourth national automobile show was held at Madison Square Garden, January 16-23, 1904. More than 200 exhibitors took space, including several foreign manufacturers. This show was held under the same auspices as the previous one. At the fourth show the vertical engine, located under the hood in front, was dominant, and the full-fledged touring car was revealing itself as the popular type, rather than the runabout with the detachable tonneau. Portents were fulfilled in 1905, and the tendency toward larger and higher powered cars became well established.

Then Came the Fifth Show.

By the time for the fifth show, which was held in Madison Square Garden January 14-21, 1905, the automobile industry had grown to such proportions that hundreds of would-be participants were unable to secure space, although 250 exhibitors were accommodated in the big building. At the shows of 1904 and 1905, the number of exhibitors was so great that the Garden was sadly crowded, and, each exhibitor being allowed to decorate his space to suit himself, the ensemble presented a motley scene of hodge podge in draperies and lighting effects. At all these

shows there was to some extent a sort of "first come, first served" policy—after the big makers were provided for—and the result was that the public was gulled to a certain degree, because every year there were upstart concerns, with experimental models, who promised great things, some booking orders, and who afterward sank into oblivion. It was seen by all that a weeding out and a discriminative exclusion would be wise, but the way to do it was what puzzled, until the problem was solved by the positive action of the veteran makers linked together in the Association of Licensed Automobile Manufacturers.

With the 1905 show, the contract between the National Association of Automobile Manufacturers, the Automobile Club of America and the Madison Square Garden Company expired, and the Association of Licensed Automobile Manufacturers obtained a three years' lease of the Garden, for the purpose of holding future shows under the auspices of the licensed makers, who were organized in March, 1903.

Now the Licensed Body Has the Garden.

Since 1905 the Garden show has been held under the auspices of the A. L. A. M., and the highly successful show there, January 13-20, 1906, was in charge of the same show committee that has the arrangements for the present one in hand, namely: George Pope, Marcus I. Brock and C. R. Mabley, with M. L. Downs secretary.

Under the new management there was a revolution in the matter of decorations, and so great a revolution was it that no affair which finds shelter in the Garden, neither horse show, ball, nor military pageant, has the gorgeousness of the annual automobile show. The lighting and decorating was put in charge of a committee, uniformity secured by not permitting any exhibitor to do a bit of decorating, and the artistic work given to a professional. Last January the old Garden presented a scene of grandeur that made regular patrons of it gape and gasp. The color scheme was white and gold, and the whole was laid out to represent an Italian garden in the summer time.

At the present seventh national show, January 12-19, the glory of the last is to be totally eclipsed. A fortune was spent in transforming the Garden into a scene of dazzling brilliancy. The general scheme is that of the Garden of a Swiss palace in early winter. The somber tones of the Garden are completely lost in the blazing glories of autumn foliage on rustic bowers, of sunset hues upon snowy peaks, and tawny fields beneath amber skies. The illusion is carried out to the uttermost and made perfect by heroic paintings at the ends and sides, which yield the spectators a grand perspective of Alpine scenery. Fountains and statues of allegorical design enhance the picture and help to furnish a setting for the jewels of the automobile industry.

Diplomats Who Will Attend the Opening Saturday Night.

From Washington will come on Saturday in a special train representatives of the embassies of Italy, Austria-Hungary, France, Great Britain, Germany, Brazil, Russia and Mexico. They will be met at the ferry with automobiles, and it is expected will reach Madison Square Garden not later than 8:30 P. M. The culminating feature of the lights arrangement will not be demonstrated until the arrival of the distinguished foreigners, the list of which is as follows:

Italy—Baron Edmondo Mayor des Planches, the Italian Ambassador and the dean of the diplomatic corps, accompanied by Count Neni-Mocenigo; Austria-Hungary—Ambassador Ladilaus Hegelmulle von Hengervar; France—M. des Portes de la Fosse, counsellor, and Lieut. de Blanpre, naval attache; Germany—Herr and Fraulein Hebbinghaus; Great Britain—E. V. Sturdy; Brazil—S. Gurgel do Amaral, first secretary; Russia—M. de Thal, secretary; Mexico—S. Balbino Valalos, charge d'affaires, his daughter, Senor Ricoy, and Mr. and Mrs. Landa Berriozabel.

After attending the opening of the show, the ambassadorial party will be the guests of the reception committee at dinner. They will remain in New York City over night.

MECHANICAL PROGRESS THAT WILL BE TOLD

By VICTOR LOUGHEED.

AT the show in Madison Square Garden there will be in evidence a mechanical progress commensurate with its splendid setting, which likewise will bespeak an advance not heretofore achieved by the industry. As never before, it is evident in the product of the thirty members of the Licensed Association that the American manufacturer has thrown down the gauntlet to his foreign competitor—and, in most cases, predecessor. The preeminence of the foreign engineer in the past has been a fact denied rather than disapproved, but now the proof is crowding close on the heels of the statement, and it is made clear in no uncertain way that the cars for the Garden show are fully capable of price, style, finish, reliability, quality, or any other kind of competition with their imported competitors.

Not the most critical mind can find any serious fault with the 1907 productions of the foremost American firms, and it is especially clear beyond all question that the biggest automobile bargains for the money are invariably American made, whatever may be thought of the less commercialized phase of the situation that achieves its successes regardless of price.

As has been increasingly apparent at each of the last few shows, the tendency towards acceptance of certain highly standardized and specialized forms is more emphasized than ever, and there is not a single manufacturer who does not present four-cylinder vertical motors in front, usually with sliding change-speed gears and drive by double chain or propeller shaft to the rear axle. Besides this most important construction there are, however, a number of motors of other type shown in the less expensive models, there being several two-cylinder horizontally-opposed motors, one horizontal single cylinder, and one vertical single cylinder. The horizontal-opposed motors are shown in both of their usual applications—longitudinally under the body and crosswise in front.

The six-cylinder engine, without having begun to sweep the field, as it is claimed to have done abroad, nevertheless is much in evidence. There is no question about the superior flexibility and torque range of the six-cylinder motor, but against this is the greater length and complication. Nothing but time can tell whether the advocates of the six-cylinder construction are destined to win general acceptance for the type they so strenuously uphold. A point that seems to give particular difficulty in the designing of these six-cylinder motors is the arranging of the intake piping, which every manufacturer arranges in a way that is peculiarly his own, showing that this detail is far from being reduced to final form and that the difficulty of feeding the cylinders uniformly is appreciated. One manufacturer goes the six-cylinderites two better, so to speak, and is placing on view an eight-cylinder motor, with the cylinders arranged in two diverging rows, constituting a typical example of the well-known V-shaped construction.

Air cooling is applied to the cars of at least four concerns, and, though it has failed to find more extensive acceptance, its continued use by these concerns—all of the highest standing and prominence—is assurance enough that it is a thorough success. Of particular interest to the novice and expert alike are the minor but not less important, refinements through which greater reliability and operating satisfaction is insured.

Water cooling departs little from practice previously established, the changes being

mostly in the direction of more liberal waterjacket spaces, larger piping, etc. The rotary gear pump seems to be displacing the centrifugal pump to some extent, while the inclosed gear drive for pumps has become all but universal.

The two-cycle engine has lost ground to the extent that one well-known maker who exhibited a car propelled by this type of motor last year has this year given it up. Against this reflection upon the merits of the two-cycle principle there is the greater success than ever before of the single manufacturer who still sticks to it, and the three and four-cylinder vertical-in-front two-cycle motors put out by this concern run with a smoothness and satisfaction not exceeded by the product of the best of their competitors.

Clutches will show a very considerable tendency in the direction of the multiple-disc, though by the use of cork inserts the cone and expanding clutches are perhaps in a fair way to hold their own. Easier working clutch springs, with smoother and more certain engagement, will be the most obvious results of these improvements.

Change-speed gears show a considerable gain for the gate-quadrant and selective-lever method of operation, which has the advantage over the progressive system of permitting the passing from any speed to any other without going through the intermediates. Four speeds ahead are the rule of all the larger and heavier cars, and in the cases where three speeds are retained, because of extreme motor simplicity or for other reasons the progressive method of operation is strongest. The simple manipulation of the individual clutch and planetary gears appeal to a number of manufacturers who evidently believe that foolproofness is a good quality for a car to possess. The most noteworthy of the planetary gears is that fitted to a large touring car of well-known make, with three forward speeds and the reverse. This gear has been used without radical change for two seasons and seems to give excellent satisfaction. The rest of the planetary gears are of the two-speed-forward-and-reverse type and are found only on the smaller cars. One example of a friction transmission is shown, applied to the smallest and lowest-priced car on the American market, which is made in a variety of styles, suitable for various classes of commercial and pleasure uses.

The propeller-shaft drive predominates to some considerable extent over its rival, the double chain, but the latter scores a point in that its use is most prominent on the cars of presumed highest quality, so the situation in respect to this phase of automobile evolution seems to strike a very even balance.

The I-beam axle section is manifestly increasing its vogue, for front axles especially, but also for rear axles where the propeller-shaft drive is in use. Here again it is evident that the dissenters from this construction feel that they have good reasons for not adopting it, in that they challenge any interested party to produce evidence reflecting upon the quality of their tubular, rectangular and other sections.

The annular ball bearing—chiefly of the Hess-Bright pattern, though neither the Mallicet & Blin nor the Standard are inconspicuous—has swept the field for certain classes of use, but in other places the conical roller bearing of the Timken people and the roller bearing of the Hyatt people seem as strongly entrenched as ever.

GODDESS OF THE SHOW.

Ignition systems are better than heretofore, and a great attention to details is apparent, but otherwise there are few changes from the constructions of previous years. The make-and-break system shows gains, but is still behind its competitor, the jump-spark.

Carbureters seem to be in a more unsettled state than any equally important element of automobile mechanism, if the variety of improvements be taken as a criterion. There are several cases in which the elaborate compensating mechanisms have been given up, but in others there is more elaboration than ever. In a couple of cases, at least, the stock fitment consists practically of two carbureters, one supplying the mixture at the lower speeds and the other coming into action only at high speeds. Despite the diversity devices all of them seem to give excellent satisfaction in use, which is, after all, the most important thing, and which simply goes to show that there are more ways than one of securing a desired end.

Especially significant, though from its very nature anything but especially noticeable, is the widespread acceptance of foreign practice in respect to the use of alloy steels for the parts on which devolve the heaviest and severest duties. It is now recognized that the merit of these high-grade materials is a question of fact rather than of opinion, and if one grade of steel will stand twice the stresses and cost little more than another, it requires only the commonest kind of good mechanical common sense to dictate its use for the vital details of an automobile.

Body designs exhibit considerable improvement, the most impressive feature of the season's development in this regard being the number of high-power runabouts, striking both in

appearance and in traveling qualities, since most of them constitute little less than genuine racing cars. A somewhat singular feature of this development is the failure of a single inclosed-body construction to appear on any of these runabouts, such as seemed indicated in the inside-driven broughams and coupés in favor a year or so ago. Both the limousine and the landaulet types are numerous, though the latter seems to be assailing the prestige of the former in some degree, apparently because of the advantage it presents in being capable of folding up, to make it suitable for both good and bad weather. The one-time popular canopy top is practically out of the running, its place having been thoroughly usurped by the folding Cape Hood. The glass front, formerly easily disposed of out of the way by folding against the canopy top, has not worked out so simply in connection with the Cape Hood, but the problem now seems solved by the expedient of folding the glass front down over the bonnet.

Accessories are numerous. It is enough to say here that a ramble through the accessory exhibits would interest the average enthusiast for as many weeks as the number of days that the show will be open. Lamps, speed indicators, odometers, ignition specialties, lubricating devices, shock absorbers, bearings, and a multitude of the other details that are essential to the fully-equipped car, all show progress.

Tires, like the materials of car construction, present few changes in outward appearance, but are confidently asserted to have gained materially in quality. Several examples of the newest tire idea—the removable rim, providing for the replacement of complete, inflated units, ready to be placed on the wheel in the briefest possible time, will be on view.

VANDERBILT CUP WINNER FOR THE FLORIDA MEET

LOUIS WAGNER, winner of the 1906 Vanderbilt Cup race, will be the star of the Ormond-Daytona meet, January 21-26. It had been expected that Demogeot, last year's winner of the speed crown, again would carry the Darracq colors in the Florida tournament, and in consequence there was considerable surprise when Wagner arrived Monday last on *La Bretagne*. A. Lee Guinness, the English owner of the 200-horsepower car which Demogeot drove two miles in 58 4-5, at the last moment was unable to sail. Therefore Wagner, driving the Vanderbilt Cup winner, will be the solitary Darracq professional in Florida, though Samuel B. Stevens, president of the New York Motor Club, expects to participate in the amateur events with the 1905 Darracq cup winner. A fast Oldsmobile flyer, with H. N. Harding at the wheel, is expected. R. W. Harroun, of Chicago, with the lightest racer ever constructed, is going to try in the high speed division. It weighs less than 500 pounds, and those

who visited the Aero Club department of the A. C. A. show will remember having seen the Harroun creation.

Five Stanley steamers will participate, Fred Marriott, of course, to figure as the pilot of the fastest one of the quintet. H. Ernest Rogers, the Brookline amateur, and F. L. Fyles, of Providence, are other steam entrants, the latter's car to be driven professionally by L. F. N. Baldwin.

The stock car entrants already include two Waynes, an American Mercedes, a Stoddard-Dayton and a Welch. The motorcycle contingent will include Curtis and Indian cycles, both concerns having something out of the ordinary for the Florida contests. Jefferson De Mont Thompson, chairman of the A. A. A. Racing Board, will be the honorary referee, and Samuel A. Miles, general manager of the N. A. A. M., will be the acting referee. It is expected that those in attendance at the Garden show will leave for Florida on the Seaboard noon trains of Saturday and Sunday.

BRITISH AERONAUTS FOR ST. LOUIS RACE.

A cable received from London announces that the Aero Club of Great Britain has decided to send a team to St. Louis to compete for the Gordon Bennett Cup. Professor A. K. Huntington, of King's College, London; Hon. C. S. Rolls, at present in America; Griffith Brewer, and J. T. C. Moore-Brabazon, all of whom figured in the first contest from Paris last year, will constitute the 1907 British team. With a full entry from Great Britain and France, competitors from Spain, Belgium and Germany, and a possibility of Italian participation, a great international race is assured. An encouraging report has been received from Washington on the club's efforts to have foreign balloons entered in the race admitted free of duty, and a definite decision is expected in a few days on the question.

AMERICAN ENTRANTS FOR BALLOON RACE.

Alan R. Hawley and William A. Hawley, of the Aero Club of America, will purchase the largest balloon allowed by the rules for the Gordon Bennett contest, and have decided to spend the early part of the summer at Paris receiving instruction in aeronautics. The Aero Club of St. Louis and another Aero Club of America will also have maximum size balloons, so that America is assured of having entrants who will not be handicapped by reason of not having balloons of the largest possible capacity.

At Cincinnati an aero club is being organized, and a request has been made to the Aero Club of America for the loan of one of the club's balloons to make trial ascensions from that city, where the quality of gas has been found to be very good.

THE LICENSED ASSOCIATION AND ITS WORK

By HARRY T. CLINTON, PUBLICITY DEPARTMENT.

THE work of the Association of Licensed Automobile Manufacturers is the most interesting factor in the great industrial field. The history of the Association is brief. In 1903 the Electric Vehicle Company secured from George B. Selden patent rights to his invention, on which he had received a patent in 1895 from the United States Patent Office. Concurrent with this transfer was formed an association known as the Manufacturers' Mutual Protective Association, with ten members, agreeing to act concertedly as regards the patent. They had recognized the validity of this patent and were anxious to pay such tribute to the inventor as he deserved. These ten, with the Electric Vehicle Company, were the charter members of the licensed association. The object of the Association, aside from protecting its members in their patent rights, was the development in the industry.

It was not the aim of the Association, as some have endeavored to point out, to cramp the industry in any form, but, on the other hand, it has tried through the co-operative methods of its members to further the industry and conserve the interest of the public, to promote confidence in trade by carefully discriminating against the manufacturer of an unmerited product, to prevent the sale and importation of cars that were not only a detriment to the industry, but to the dealer and user alike, and to forestall the flooding of the market with a cheaply constructed car to be forced on the often non-discriminating buying public. At the time of the organization one of the officers expressed himself as follows, which thoroughly demonstrates the position taken and the attempt to conserve the interest of the public as well as the legitimate manufacturer and dealer:

"It is not the intention to make the Association a 'close corporation.' On the contrary, its money will be expended and the efforts of its officers put forth to further the best interests of the automobile business and prevent abuses. It will be our object to improve the standard of the American automobile and to see that purchasers get full value for their money by putting a check upon any 'wildcat' or get-rich-quick promotions. There is noticeable even now a tendency on the part of irresponsible persons to copy devices which established makers have spent thousands of dollars to perfect, and to assemble in the end a trashy article that sells on looks and will not give satisfaction. There is a tendency on the part of men having small machine shops to put up flimsy engines and carriage bodies and dispose of them, which they are now enabled to do because of the demand for automobiles exceeding the supply. This sort of business the Association can and will stop. It will not try to shut out reputable and established manufacturers, who build a reliable vehicle; it will license all such, but it will license no unreliable upstarts. In this way the Association will protect the public and be a boon to all purchasers of gasoline automobiles."

To carry out the proposed ideas of the Association, its first step was the establishment of several departments or branches, the first inaugurated being the Mechanical branch. The organization of the Mechanical branch may be considered not only the most important step taken by the Licensed Association, but the action stands pre-eminent in the whole automobile industry. The two things accomplished by the branch which are especially significant to the user are the increased quality in construction and the standardization of parts.

Mechanical Branch.

The branch numbers nearly 100 engineers and factory superintendents, all of whom have had years of experience in the manufacture of gas engines for road locomotives. The members meet once or twice a month for the discussion of the best means of automobile construction and development. Without doubt, the

open and frank talks on specific mechanical subjects at these meetings are productive of results that otherwise could not be obtained. At first these meetings were somewhat constrained, but it soon developed that the other fellow had some ideas that were worth knowing.

There is no branch of any manufacturing industry that requires quite so much experimentation and as many tests as that of the automobile. Recognizing the fact that owing to the expensive experiments and tests necessary and that the lack of time often prohibited the individual manufacturer from making the many researches, a mechanical branch was established at Hartford, under the direction of an expert metallurgist. The laboratory is equipped with the latest testing machines, and extensive experiments and tests on engines, metals, oils, tires, and, in fact, in all parts not thoroughly developed in automobile construction, are continually going on. The association recognized that a car constructed of material scientifically correct was necessary if the confidence of the public was to be gained. Standards for various metals to be used in specific parts, which after repeated experiments were found to be correct, were adopted. Specifications for metals were compiled and the use of these specifications resulted in a stronger and more elastic steel being made. The co-operation of the American steel manufacturers was sought and received, the steel makers being ready to furnish a better grade of material if it could be made of uniform specifications and in quantities which would permit of better grades. Heretofore the grade of steel used by foreign manufacturers was considered superior to the American make, but it may be unreservedly said that, through the specifications adopted by the Association, from a point of material used now, the American product equals, and in some cases is a higher grade than, that now used by many foreign manufacturers.

GRACEFUL MOORISH TOWER
THAT SURMOUNTS SHOW.

The other elements of standardization can be termed a boon to the user. The adoption of the A. L. A. M. screw standard is recognized as one of the most important steps taken in the automobile industry to avoid the annoying trifles that often cause so much trouble to the user. Every driver of a machine knows what it means to be stranded by the stripping of a nut or bolt and the additional aggravation by finding when he reaches a repair shop that the desired article is useless on account of the varied pitch of the thread or the size of head of a nut. Uniformity, not only in screws and bolts, but in spark plugs, will facilitate the work of any automobile owner.

Many subjects have been discussed by the branch which have a decided bearing on the future methods of automobile construction. Subjects under discussion are carburetion, engine vibration, oils, shock absorbers, detachable and interchangeable tires and rims, piston rings, ball bearings, elimination of noise and the use of alcohol as a fuel. The subject of alcohol is at present receiving the immediate attention of the test committee and some interesting reports are expected at the January meeting, scheduled for Tuesday and Wednesday of show week.

Traffic Department.

Another department of particular interest, not only to the manufacturers but to the users, is the Traffic branch. It is generally known that the transportation of automobiles has become one of the chief sources of revenue to the railroads to-day. The department has been instrumental through its manager in obtaining better rates on nearly all classes of automobile traffic.

It suggests and assists in the routing, not only of the product of its members, in such a way that better rates are obtained, but it facilitates the handling of the product, insuring in many cases a safer and quicker delivery. Reduced rates on parts and many reclassifications of benefit both to the manufacturer and railroads is the result of the untiring efforts of the department. The adoption by the railroads of suitable box cars with large side doors is a feature that must not be overlooked. Heretofore the side door of the ordinary box car was too small to admit of an entirely assembled machine, and it was found necessary to take the automobile apart for transportation, and in many cases to the detriment of the machine, as it could not be put together at its destination with the same skill as that at the factory, with the natural result that the user, as well as the dealer, did not get the full benefit of the factories' experts.

Agency Department.

The Agency department of the association is an important factor in the selling end of the industry. By terms of the license agreement, manufacturers are not allowed to market their product through any dealer handling unlicensed cars and thereby aiding or abetting the manufacture or sale of cars manufactured by infringers of the Selden patent. Through the work of this department violations which necessarily would be a detriment to the industry as a whole have been avoided and the manufacturer and user alike benefit by the guarantee of the quality of the dealer. The department has been instrumental in arbitrating many small controversies of its members and helping to secure reliable men for all branches of the industry. Records of cars manufactured, sold and used, not only by the association members but by other manufacturers, are kept, which will prove a most important document upon the decision of the pending suits.

The work of the association has been progressing rapidly, endeavoring in every way to direct and guide the industry along a sound and conservative path and, through the merits of the cars produced under its standards, point out to the nondiscerning buyer the cars that have come to stay. Aside from retaining the public's confidence in the industry by the manufacture of a meritorious product, it has relentlessly endeavored to protect the buyer from being "bitten" by what some one has very rightly called the "fly by night" importers and mushroom manufacturers. Like every new industry, as soon as a certain amount of popularity has been attained, every Tom, Dick and Harry thinks he is qualified to be a manufacturer, not taking into consideration the lack of experience and, in many cases, the lack of substantial backing. A few experimental cars are made, exhibited and finally unloaded on the unsuspecting buyer, who afterwards, as a rule, will do all the experimenting on the car, in an unsuccessful endeavor to make it do the work required of it; and so with the importer who, with a model to take orders, often unloads a cheaply constructed car and returns home, leaving the purchaser to alleviate his thoughts by condemning the industry as a whole.

Some interesting statistics prepared by the association show to some extent what might be the result if action was deemed unnecessary. In the past five years it is shown that 367 corporations and individuals have incorporated or organized for the purpose of the manufacture or importa-

A SWISS GUARD.

In this spick and span manner the Garden attendants will be faultlessly dressed.

tion of automobiles who have been notified of their infringement of the Selden patent. Of these 367 it is found that there remain in the business, actually making, exhibiting or advertising, only 111, showing the number who have ceased to be 218; the balance constituting importers, largely partnerships and individuals, doing small business, totals 38. Of these importers the total number ceased are 15, leaving 23 still in business. When it is considered that the leading American makers constitute the licensed group, all of whom have been in the business for years, and that the 32 members produce 81 per cent. of the output while 60 manufacturers of unlicensed cars produce 11 per cent., what will become of the 73 manufacturers producing only 8 per cent.?

In the meantime it must not be forgotten that the basic Selden patent is behind the Association of Licensed Automobile Manufacturers, and while part of the association was aiming for a "car perfectum," the prosecution of the suits against the infringers of the patent has not abated. As said in a recent issue of a motor paper, the attitude of the association and its attorneys has not been to

try the case in the newspapers, but through the proper channels provided by the United States patent laws. However, a régime of the court proceedings of this already famous case may be of interest, especially at this time, owing to the proximity of a final decision in the proceedings. In 1879 Selden filed specifications and applied for a patent on what the patent office considered the pioneer invention of a gas engine for road or horseless carriage use. In 1895 the patent was granted the inventor. In the Commissioner of Patents' annual report in the *Patent Office Gazette* for May 12, 1896, the attitude of the patent office is clearly defined: "Selden in 1895 received a patent, November 5, No. 549,160, which may be considered the pioneer invention in the application of the compression gas engine for road or horseless carriage use." At the time many of the manufacturers of gasoline automobiles recognized not only the validity of the patent, but elected to acknowledge the genius of the pioneer of the courageous prosecution of a new art.

In 1900 suit was brought against the Buffalo Gasoline Motor Company for infringement of the patent, resulting in Judge Hazen's decree in sustaining the patent and holding that the defendants had infringed. The same year the Winton Motor Carriage Company was prosecuted for infringement; Judge Coxe overruled the demurrer of the defendants with an opinion most favorable to the patent. Suit was brought against the Automobile Ford Carriage Company and the Raulitz Automobile Company, the former in 1900 and the latter in 1901, resulting in the complainants being granted perpetual injunctions and accountings. In 1903 suit was filed against the Ford Motor Company, as manufacturer, John Wanamaker and C. A. Duer as dealers, and O. J. Gude as user, for infringement. These are the so-called

test cases upon which a decision is being awaited with some intrepidation by those whose beliefs have not led them to recognize a monopoly granted by the United States Patent Office. That a decree is expected soon is generally understood, for the last witness of the complainants is nearing the end of cross-examination, after which, with suitable time for the preparation of briefs and arguments, the case will be presented for trial in the United States Courts having jurisdiction over same.

FATHER NEPTUNE'S KINDLY FACE ADORNS THE FOUNTAIN'S BASE.

TREND OF DESIGN THAT WILL BE REVEALED

By C. B. HAYWARD.

JUST what the automobile of 1907 is to be like, is something that will serve to attract thousands of people to Madison Square Garden during the coming week. Even at this late day there is the usual crop of ante-show prophecies, those hardy annuals about automobiles being vastly cheaper, and the arrival of the "poor man's" car, that make their appearance as faithfully at this time as does the picture of the interior of a German toy factory just before Christmas. In view of the present widespread state of education concerning things automobile that prevails, it is hardly probable that many people are still deceived by talk of this kind, which for the most part has been dropped by all except the most poorly informed disseminators of alleged news. Suffice it to say that all who go to the show looking for the cheap car, or the automobile that sells for next to nothing, and which can be maintained for nothing at all, are bound to be disappointed to a greater extent than ever before, for prices, instead of declining, have risen. It is not merely that American makers are turning out bigger cars; they are manufacturing better cars, better not alone in design, but better by far where material is concerned, and materials of the quality now employed are costly. For that reason the cars of 1907 will come higher than their predecessors in many instances, but they will in turn represent a higher value for the money than has been offered the purchaser in the past.

Very Few Radical Departures to Be Shown.

Where novelties are concerned, probably the most radical thing to be staged will be the gasoline-electric chassis of the Electric Vehicle Company. It represents one of the many expedients adopted as a stepping stone toward the "gearless" car, which is the aim of so many designers, and though it is an old story abroad, numerous experiments having been made in this direction and a car actually placed on the market during the past year, this is the first car of its type to see the light on this side of the Atlantic. Its appearance is not merely tentative; its builders are showing it, not as a curiosity to attract attention, but to take orders for duplicates of it, for it has only been uncovered to the public after eighteen months of constant experimenting and trials under actual service conditions in order that any defect of design or construction in the slightest detail would be certain to manifest itself. Not until this was established beyond a doubt did its builders decide to place it on the market, so that the chassis which will be placed on view represents the successful culmination of their labors.

Another vehicle that is bound to attract considerable attention of a favorable nature is the "waterless" fire engine. It is not, technically speaking, a fire engine, but more in the nature of an auxiliary fire wagon which has been used by the Springfield, Mass., fire department during the past half year with telling effect. Strictly speaking, it is not a commercial vehicle in any sense of the word, though on the other hand it can hardly be termed a pleasure car. It is a 40-horsepower Knox "waterless" touring chassis, upon which a body specially adapted to the purpose has been mounted, and its speed and lightness, combined with a generous carrying capacity, have proved its most valuable attributes. Its appearance at the show has far more significance than that of being merely an exhibit that is somewhat out of the ordinary and hence a drawing card for the curious; it presages the dawn of an era when all fire apparatus will be motor propelled and as such represents a type that will have many followers in years to come.

Where both motor and vehicle design generally are concerned it will be necessary, as has come to be usual during the past two or three shows, to look for those refinements of detail to which improvements and alterations are now largely confined. That is, with the exception of one or two instances of revolutionary

changes in motor design such as that of the Pope-Toledo 50-horsepower car, which represents a totally new departure from standards hitherto adhered to by the makers of the latter. Conforming to what is considered as an advanced form of construction, the valves are placed in the head, in this case at an angle, and though the opposite disposition has been retained, but a single camshaft and set of cams is employed, the valves being operated by means of walking-beams actuated by pushed rods which are moved in turn by cams cut with a profile that raises the rod in order to actuate one valve and permits it to drop under the tension of a spring to operate the other. Though slow in gaining recognition, the influence of this form of valve placing has been gaining ground.

The principle of offsetting the cylinders from the center of the crankcase, though as old as the automobile motor itself, as it was a feature of one of Daimler's first V type motors, is something that has again come in for consideration. It has been adopted in the case of the Thomas 40-horsepower car, which will make its debut at the Garden show, though it is already quite well known where the public is concerned, having been on the road to the extent of quite a number of cars during the past few months. The amount of offsetting in this case is one inch; in the Northern, 3-4 inch. The new Winton 40-horsepower car, which is the heaviest car ever turned out by this house, also embodies the same principle.

Multiple Disk Clutch Has Gained Ground.

Another trend that has developed strength to a very considerable extent during the year intervening since the last show is the adoption of the multiple disk clutch. This will be found on a larger number of cars than ever before, and the slow but steady growth it has had would seem to be indicative of lasting popularity with both the designer and the owner of cars thus equipped. The selective type of change speed gear has likewise found more favor than previously and now outnumbers the straight or progressive sliding type, while the same is true of the propeller shaft drive as compared with the side chain type, the use of the former becoming more and more general and on cars of higher powers than has hitherto been the case, refinements of design and improved construction having made it possible to overcome most of the defects primarily urged against this form of drive. On the other hand, the advocates of the side chain drive have awakened to what appears to be its chief, if not only, drawback, that of constant wear and noise due to its exposure to the flying mud and grit of the road, and have accordingly undertaken to encase the side chains, an example of this being found in the Lozier.

The controversy over the relative merits of the four and six-cylindered types of motors, which is still smoldering, has served to keep interest in this question at a high point, though the lack of new adherents during the past year would seem to favor the upholders of the four, as the Pierce Great Arrow, which made its first appearance in the Glidden Tour, is the only addition. This, together with the Stevens-Duryea in two models and the Franklin air-cooled six-cylinder car, will constitute the showing of this type. The *pièce de résistance* in this field will be the Hewitt eight-cylindered car, rated at 60 horsepower, which marks the extreme development that multiplication of the cylinders has attained on this side of the Atlantic. Its presence at the Hewitt stand will be more striking owing to the fact that the only other type exhibited by the same maker will be a car of the single cylinder type equipped with a touring body. Brakes have also come in for considerable attention, though here, as in other things, improvement is to be looked for in detail.

This tabular presentation of the show will be studied with great interest, for it tells much and quickly.

*NOTE.—In order to avoid confusion by unnecessarily encumbering the table, the progressive or straight sliding type of change speed gear is merely designated as "sliding," and the selective type as "selective" only, the following numeral in each case representing the number of forward speeds, it being understood that there is always a reverse. For the same reason a multiple disc type of clutch, being designated as "disc," though on light runabouts with planetary change speed gear a single disc is usually employed. Where two sets of figures are given under tires, the smaller are those of the front wheels and the larger those of the rear. Where a runabout and touring car of the same make are listed together, the specifications given apply to both, except where separate figures are given, in which case the upper applies to the runabout.

*Simplex. Price of 30-35 horsepower touring varies according to cost of body, that given being the minimum. Chassis alone sells at \$4,950. Wheel-bases given are optional.

*Stearns. 30-60 horsepower. This is explained by the fact that a special system of carburetion has been made a feature of the motor. It consists of a small and a large carburetor fed from a common float chamber. On the small one the motor develops 30 horsepower, the large not coming into service until the small one is fully open. Control is by the usual throttle lever.

NOTE: Carbureters.—This head has been omitted altogether, principally from the fact that it would be impossible to set forth briefly the differences in the various types used by different makers, beside which the majority describe their carbureters as "automatic" or merely as "float feed" or again the "best," none of which convey any great amount of information.

Ignition.—Except where a magneto is mentioned, it is to be understood that the current is supplied by accumulators, one or two sets being employed, though on the lighter cars dry cells are employed as a reserve. Where the numeral 2 follows the statement of the ignition it indicates that two entirely independent systems are employed. "H. T." and "L. T." refer to high and low tension.

General.—Under the head of valve operation "direct" means with the usual push rods and tappets, and "rocker arms" by overhead arms or walking-beam. Under lubrication "mechanical" refers to a motor-operated type of force feed oiler, the numeral following giving the number of independent leads. The numeral following the type of change speed gear, such as "Selective 4," indicates the number of speeds forward. Under engine bearings "plain" is merely stated in distinction to ball bearings where the maker has not supplied more definite data, such as bronze, babbit, alloy, etc.

PREDETERMINATION OF MAXIMUM MOTOR POWER*

BY R. ARNOUX, VICE-PRESIDENT TECHNICAL COMMITTEE, AUTOMOBILE CLUB OF FRANCE.

ACCURATE predetermination of the maximum power of an internal combustion motor of given dimensions is a subject of great interest for the organizers of great racing events, both for cars and motor boats, as well as for designers. For the engineer and the manufacturer this interest is represented by the knowledge he wishes to have of the maximum output, which, by means of the usual conventional modifications of design, he can hope to obtain from a motor of certain dimensions, or one having a cylinder of a given cubic capacity. For the organizers of racing events, the subject is of interest, in that it provides a means of equalizing the chances of the various competitors in the same event by giving a basis for a handicapping system.

As this power is at once the result of the pressure developed by the explosion of the volume of the cylinder in which the explosion takes place and the angular velocity of the moving parts, it would appear impossible, *a priori*, to establish any formula permitting the determination of this maximum power output with a degree of precision sufficient for practical purposes, where only the cylinder volume or one of its dimensions is known. But this apparent impossibility disappears when the philosophy of the internal combustion motor is examined more at length, as we shall do here. Internal combustion motors all possess a common characteristic, that of drawing from the surrounding atmosphere, of which the pressure, and in consequence the density, are constantly varying, the oxygen necessary for their operation. On the other hand, it is not the bulk of the air thus drawn in that produces combustion, and in consequence the complete utilization of the combustible gaseous mixture, but an invariable proportion between it and a given amount of fuel. This, in the case of ordinary petroleum spirit, or gasoline, is one part gasoline to 15 parts air by weight, that is, 12 cubic liters of air to one gram of gasoline, this proportion permitting of the disengagement of the maximum amount of heat obtainable by the most efficient utilization of this combustible.

This established, we may take up the subject of determining as accurately as possible the exact influence of the different factors that limit the maximum power output of the internal combustion motor. It is well known that the energy developed by a gaseous mass, in passing from the volume v to volume V , is equal to the integrated value of the product of the pressure p , by the corresponding elementary variation dv of the volume. That is to say:

$$\int_v^V p \, dv$$

In explosion motors, this quantity of energy, that is, indicated power, is valued by a diagram traced in rectangular coordinates, across which the abscissæ are proportional to the course of the piston, and the ordinates to the corresponding pressure. The spaces on this diagram are determined with the aid of a planimeter, and if these spaces are given by the instrument in square millimeters, for example, it will suffice to divide by the length of the maximum abscissa, measured in millimeters, to obtain the mean value of the Pm of the pressure. This mean pressure is that which must be constantly exerted on the head of the piston in order that it may develop the same amount of energy. Since v designates the volume at the end of compression, that is, the initial volume of the gaseous mixture; and V , the volume at the end of the stroke, there is as the value of the preceding integral between the limits v and V :

$$\int_v^V p \, dv = (V - v) P_m \quad (2)$$

Now the volume $(V-v)$ is none other than that generated by the piston during the total length of its travel, that is to say, the *cylindrical* volume, and it will be plain that the amount of

energy developed by each cylinder will be equivalent to the product of its volume by its mean pressure.

The Interesting Phenomenon of Expansion.

This last relation is interesting in that it tends to foster experiment resulting in the reduction to a minimum of the initial volume v of the explosive mixture and in consequence of the use of the highest degrees of compression possible short of causing spontaneous combustion, in order to extract from a given quantity of gas the maximum amount of energy available. A slight digression may be made here from the question of how to determine the maximum power that a motor of a given cylinder capacity is capable of developing, to recall what we said in 1903 at the Second International Automobile Congress, in our report on the subject of ignition, relative to the employment of high compression. The explanation of this growth of power with the compression, as illustrated in practice with gas engines, is very simple. It is, in fact, the phenomenon that permits us to *transform into work* all, or, more generally speaking, a part of the heat contained in an elastic fluid. This phenomenon is that of expansion. A gaseous fluid is a spring that may be tightened to advantage in heating it, and which cools upon expansion after having produced its energy. The fall in temperature, and in consequence the partial disappearance of the heat as the result of the expansion, represent the means employed by nature to pay for the work created. Regarding the quantity of heat transformed into work, this is regulated by the degree of expansion that is permitted it. The greater the degree to which it is allowed to expand, the greater the amount of energy that can be extracted from it, but in carrying the expansion to excess the variation of the initial volume of the gas during the stroke is made to alter within extreme limits. It will be quite evident that this extreme variation of volume cannot be realized in motors in actual service without the employment of an excessively high compression, that is, by further reducing, as far as practical, the volume of the gas to a point where it is subjected to a degree of heat equivalent to almost instantaneous combustion (explosion), or progressive combustion (Diesel motor), in order to convert a minimum initial value to one as high as possible. It is well to observe that the degree of expansion does not depend at all on the relative amount of travel of the piston (contrary to the generally prevailing opinion), but solely on the relation that the initial volume (at the end of the compression stroke) bears to the final volume of the gaseous mixture.

Some Advantages of High Compression.

The advantage, from a thermodynamic point of view, of the employment of high compression, or, to put it in another form, an extreme variation of volume of a gaseous fluid, may be readily calculated in a case where both the compression and the expansion are adiabatic, by which the amount that they can accomplish in a very short time can better be calculated, this being the case of the automobile motor with its extremely high angular velocity. Under these conditions, there is obtained, as an expression of the energy developed, the equation in which:

$$W = Eq \left[1 - \left(\frac{p_1}{p_2} \right)^{\frac{k-1}{k}} \right] = Eq \left[1 - \left(\frac{v}{V} \right)^{k-1} \right] \quad (3)$$

In this E is the mechanical equivalent of the calories, q the total quantity of heat generated by the explosion, p_1 and V , p_2 and v , the pressures and volumes of the gaseous mass at the beginning and the termination of the phase of compression, and k the ratio $\frac{C}{c}$ of the thermic capacities at constant pressure and volume, a ratio that does not vary sensibly, notwithstanding that it is subject to an increase of capacities with the temperature.

*Translated from "Bulletin Officiel de la Commission Technique."

These two equations show that the *thermodynamic product*

$$\frac{W}{Eg} = 1 - \left(\frac{p_1}{p_2}\right)^{\frac{1}{k}-1} = 1 - \left(\frac{v}{V}\right)^{k-1} \quad (4)$$

will be much greater, if the compression p_2 of the mixture is carried further, or its initial volume v correspondingly reduced with regard to the volume V at the end of expansion.

Experience has constantly demonstrated the economy to be gained with high compression, or, to put it in another way, an extreme variation in the volume of the gaseous mixture. In the first Lenoir gas engine the expansion was in the ratio of but 1 to 2, and the fuel consumption amounted to 3,000 liters of illuminating gas per horsepower hour, while in the Cateau motor, experimented with by M. A. Witz in 1903, this was reduced to 368 liters. the expansion or variation of volume being in the ratio of 1 to 6.

Greatly Reduced Fuel Consumption.

The fuel consumption in the case of gasoline motors has followed a similar march of progress, dropping from 1,100 grams per horsepower hour in the case of some of the earlier models in which the ratio of expansion was 1 to 3, to 180 grams of low grade oil in the four-cycle Diesel motor, in which a variation of 12.5 to 1 is attained, corresponding to a compression of 35 atmospheres. In the case of motors in which the carburetion of the charge is effected prior to its entrance to the cylinder, it is evident that carrying the compression to such an extent is not possible by reason of the fact that spontaneous combustion would take place long before such a high value was reached, and this is exactly the factor that limits the quantity of heat that is transformable into energy in this type of motor. But the compression of a gaseous mixture, when carried to such a high value as to render ignition by means of spontaneous combustion practical, presents the double advantage of rendering every mixture explosive, regardless of how poorly it may be carbureted. This fact is one that permits of a rational regulation of the engine, that is, economically, as in the Diesel motor, in which the amount of power developed is regulated by means of the degree of the carburetion of the charge, thus doing away with the necessity of advancing the point of ignition with all its inconveniences, a further advantage being found in the instantaneity of the burning of the mixture under the high compression actually employed in these engines, as revealed by indicator cards.

On the other hand, it is well known that the *density*, or, what amounts to the same thing, the pressure of an explosive mixture, is feeble, while the rate of propagation of the explosive wave is slow. This is such that in mines containing firedamp it has been frequently established by the miners that the speed of the propagation of the flame does not exceed the pace of a man walking slowly, which is less than 3.6 kilometers per hour, or about 1 meter per second. MM. Mallard and Le Chatelier have observed the same thing under conditions that are comparable in every way with those found in the explosive motor, that the speed of the propagation of the flame does not exceed .25 meter per second in weak mixtures. If, on the contrary, the explosive mixture is compressed to a point three times higher than that at which spontaneous combustion occurs, the least rise in temperature, and in consequence in pressure, is sufficient to fire it *simultaneously in every part*.

Speed of Flame Propagation.

The experiments of MM. Vielle and Berthelot have demonstrated that in such a case the explosive wave may attain a speed of 2,000 meters per second, or almost six times more than is possible in the open air. To resume, it may again be stated that, in augmenting the compression, the thermodynamic product of the motor is increased, and, as we have already seen, the necessity for advancing the point of ignition with all its inconveniences is totally done away with. Besides which, there is reduced just at the moment when it is most necessary that action of the walls of the combustion chamber, which designers have really been striving to augment by placing the inlet and exhaust valves in chambers or pockets, the surface of the walls of which is nearly double

that exposed to the action of the incandescent gas, where the valves are located in the head of the cylinder—an expedient that has already been adopted by several progressive designers.

We have already seen that the amount of energy developed by the explosion of a mass of gas during the total piston travel is equal to the product of the mean pressure developed by the variation of the volume of that mass. But in practice it is not sufficient merely to produce this work; it must be produced in the shortest possible time. It is quite evident, in fact, that a motor running ten or twenty times faster than another will accomplish in that much less *time* the same amount of work, and the rapidity of its work will be ten or twenty times greater.

It will not be amiss to dwell somewhat here, after our colleague, M. Hospitalier, on the distinction between the terms force, work and power—mechanical quantities that are quite distinct, but which are only too often confused to-day, not alone in current conversation but in technical writings. A *force* cannot be utilized industrially, except in as far as it is capable of producing displacement or change of position; of overcoming the resistance which is opposed to it. The product FL of this displacement L by the value F of the force exerted following the displacement is the measure of the work effected. The quotient of this work FL , by the time T employed in its execution, is the measure of the *speed or activity of the work*, or, to perpetuate an expression, the *power* of the motor may be equally well defined and measured by the product of the *force* by the *speed of displacement* at its point of application. If a comparison be permissible, we should say that the *work* is to the *power* as the *task* of effecting it is to the *rate* of its execution of that task, with relation to the time.

The work produced by the explosion motor is essentially *spasmodic*, or *periodic*, the *mean power* P being equal to the quotient of the work of the cylinder divided by the length of the period of its cycle T , which is determined by the formula:

$$P = \frac{(V-v) p_m}{T} \quad (5)$$

Influence of the Time Element.

If we designate by n the number of cycles effected by the motor in a given unit of time, a second for example, it is clear that the relation of the unit to the duration T of each cycle is identically the same as that of the relation that the number of cycles n bears to the time unit, as a result of which we have the formula:

$$\frac{1}{T} = \frac{n}{1''} \quad (6)$$

from which the mean power developed by the motor may be defined as equivalent to the *periodic work* by the product of that work times its frequency n . This frequency n , with which each cylinder repeats its stroke, may be readily deduced from the angular velocity of the motor. If it be observed that the motor is making ω r.p.m. its speed in turns per second will be equal to $\omega : 60$ turns per second, and as each actual cycle of the motor calls for two turns of the crankshaft, the frequency n of the work of each cylinder is equal to $\frac{\omega}{2 \cdot 60}$ and the power developed is expressed by the formula:

$$P = (V-v) \cdot p_m \cdot \frac{\omega}{2 \cdot 60}$$

or by

$$P = \frac{\pi D^3}{4} C \cdot p_m \cdot \frac{\omega}{2 \cdot 60} \quad (7)$$

in which D and C designate respectively the diameter of the piston and its total travel.

The total power developed by an explosion motor of given cylinder dimensions depends, then, upon two variables, the *mean pressure* p_m , and the frequency $\frac{\omega}{2 \cdot 60}$ with which the periodic work is repeated in that cylinder, and this is proportional to the angular velocity of the motor. It is clear that if the mean pressure be

constant the power developed by the motor will be proportional to its angular velocity. But experience has shown that this mean pressure, far from maintaining a constant value, continually decreases in proportion as the speed increases, in such a manner that the product of these two variables, which regulate the power of the motor, passes a maximum. This decrease in mean pressure is in evidence on indicator cards taken of the cycle, and drops as the speed of the motor increases, owing to the decrease of the couple or motor moment, exercised by the latter, which is equal to that mean pressure as may be readily demonstrated.

If this be designated by n , the product of the motor, or, rather, the relation that the power P' , developed at the crankshaft, bears to the indicated power P , then we have the equation

$$P' = \eta P$$

The power P' developed at the crankshaft is equal to the product of the work per turn (which is equal to the product of a certain force F applied tangentially at a distance L from the axis of the motor, by the length of the circular path traversed in one turn by its point of application) by the number of turns $\frac{\omega}{60}$ made by the crankshaft per second. This gives us:

$$2 \pi L \cdot F \cdot \frac{\omega}{60} = \frac{\pi D^2}{4} C \cdot p_m \cdot \frac{\omega}{2 \cdot 60} \cdot \eta \quad (8)$$

or, since the factor ω is common,

$$2 \pi L \cdot F = \left(\frac{\pi D^2}{4} C \right) \frac{\eta}{2} \cdot p_m \quad (9)$$

Now the product FL of the force F by the distance L of the axis of rotation measures the value of the couple or motor moment developed, and the formula (9) demonstrates that if the output η of the motor be constant its couple FL , or the work per turn $2 \pi FL$ is simply proportional to the mean pressure p_m , or the mean effort $\frac{D^2}{4}$ exerted against the head of the piston, and consequently to the work

$$\frac{\pi D^2}{4} C \cdot p_m$$

developed by the cylinder.

It will suffice to determine experimentally, for example, the relation between the work per turn of the motor crankshaft to its angular velocity, to learn what relation the work of the cylinder bears to that same angular velocity. This relation is illustrated by the curve $M' M'' M'''$ of the chart Fig. 1, taken in 1903, on a motor capable of developing 18 horsepower, and published by us at that time in *La Vie Automobile*. The experimental determination of this curve is very simply effected by varying the pressure of the brake and in measuring the angular velocity in turns per minute, for example, corresponding to the value of each

change of brake pressure. It is clear that the resulting curve reaches its maximum value corresponding to the resistant moment opposed by the brake shortly after the minimum speed that the motor can maintain is reached, and this moment constantly diminishes thereafter in proportion to the increase in angular velocity. Now, as the formula (8) demonstrates that there is a fixed ratio between the value of the motor moment and that of the work of the cylinder, which is evident, all things being otherwise equal and proportional to the quantity, or, more exactly speaking, to the mass of the gaseous mixture drawn in for each explosion, it is at once evident that the motor inspires less and less in each cylinder in proportion to the increase in the angular velocity. The charges, sufficiently voluminous at the start, become less and less copious.

And what does this indicate? Simply this, that if the depression produced by the downward travel of the piston increases with its linear speed, and in consequence with the angular velocity of the motor, on the contrary, the duration of the refilling of the combustion chamber is inversely proportional to that same angular velocity. Now, if the weight, or, more accurately speaking, the mass of the explosive mixture aspired were the direct function of the speed of displacement of the piston and inversely of the duration of the inspiration, it could easily be conceded that the mean mechanical effort set in motion by the power cylinder reached a maximum at a certain value of the angular velocity, which is the same as that corresponding to the maximum power developed by the motor at its crankshaft.

This last may be easily deduced by an extremely simple graphic calculation of the curve of the moment or motor couple. In fact, we have already seen above (equation (8)) that the power P' , developed by the motor at its crankshaft, is equal to the product of the work per turn by the frequency $\frac{\omega}{60}$ or $\frac{10\omega}{600}$

$$2 \pi L \cdot F \cdot \frac{\omega}{60} = P' \quad (10)$$

which gives us the equation:

$$\frac{P'}{2 \pi L \cdot F} = \frac{10 \omega}{600} \quad (11)$$

If we raise to the point having for abscissa 600, the ordinate 600 S, and project on that ordinate all the points of the curve $M' M''$, so that M'' corresponds to the abscissa of 800 turns per minute, and then join the origin at the point projected M'' , by a straight line terminating at W'' on the ordinate 800 M'' , the triangles $o(800) W''$ and $o(600) M''$ will give the proportion

$$\frac{W''(800)}{M''(600)} = \frac{o(800)}{o(600)}$$

which is none other than the proportion (11). Moreover W'' is a point of the characteristic curve of the power developed by the motor at its crankshaft. This was also determined by the points $W' W'' W'''$ of the power characteristic of the motor experimented on. It will be seen that this power increases proportionately to the angular velocity by the small values of the latter; then it passes a maximum, after which they decrease constantly. It will be equally evident that if the mass of the explosive mixture were constant and independent of the speed, the same would be true of the couple or the moment, and the power developed, of which the curve would be represented by a direct line, such as OP , would be proportional to the angular velocity of the motor.

(To be continued.)

Now it is the "air hog" who is causing trouble in England instead of the time-honored road animal of the same breed. He is the balloonist, who, with dragging anchor or other appurtenances peculiar to aerial navigation, does damage to windows, hothouses, fences, shrubbery and lawns, and does not pay up for the damage he causes the suburban resident. It is already proposed to make balloonists carry numbers on their airships, so that they may be identified.

FIG. 1.—The figures 5, 10, 15, 20, etc., represent the angular velocity of the motor in turns per second, and the figures 0, 200, 400, etc., in turns per minute.

A NEW FORM OF TIRE CONSTRUCTION.

With a view to overcoming the tendency to disintegrate inherent in some forms of pneumatic tires, this being caused by the bending or crinkling of the tire body where the latter flattens against the road surface due to the weight of the load, F. A. Bragg, of Springfield, Mass., has invented a form of tire construction in which the various layers of material are mechanically bound together in addition to the vulcanization, this being done subsequently in the ordinary manner. As the bend in the

CROSS SECTION OF THE BRAGG TIRE.

movement of the layers of fabric to a minimum, the body of the Bragg tire is quilted by sewing, as will be apparent from the accompanying illustration, which pictures its construction. This is done before the vulcanizing process is carried out and the thread or cord employed is previously permeated with a substance which, when the tire is finished, causes the former to become permanently adherent to the tire body. The quilting serves to reduce the area in which movement of one layer of fabric may take place relative to another to the space located between adjacent lines of stitching, no less than 16,000 stitches being required to complete a single outer shoe.

the tire wall mentioned is constantly being shifted circumferentially by the rotation of the wheel, every part of the fabric layers and their binding element is subjected to a great strain, eventually resulting in the separation of the various constituent layers of the tire body due to the working of one upon the other, or the tendency toward such movement set up by the strain in question.

To overcome this defect by means of a binding auxiliary to the cementing effect of the rubber in order to reduce the relative

THE SOCIETY OF AUTOMOBILE ENGINEERS.

The annual meeting and dinner of the Society of Automobile Engineers will be held at the New Grand Hotel, Broadway and Thirty-first street, Thursday, January 17. The meeting will be held at 2 P. M., and in addition to the election of officers and a general discussion the following papers will be read: "Simplicity," by Henry Ford; "Some Facts Pertaining to Electric Ignition," by Henri G. Chartain; "Some Features of Construction," by Thos. J. Fay; "Alcohol," by Thos. J. White; "Change Gears and Their Journals," by Henry Hess. The dinner is scheduled for 7:30 P. M., and members may invite guests.

A TECHNICAL NEWS BUREAU ESTABLISHED.

A bureau has been established in New York City to supply articles on the design, construction, sale and use of automobiles to the automobile and popular press. Arrangements have been made with a corps of experienced writers to prepare such matter upon demand, so that the requirements of an editor in any phase of the subject can be filled at short notice. Among these writers may be mentioned Herbert L. Towle, W. P. Stephens, Joseph Tracy, Harold H. Brown and Thomas L. White. Arrangements have also been made with Edwin Levick and Nathan Lazarnick to supply photographs especially taken to accompany the manuscripts. The organization is known as the Technical Press Bureau, and offices have been opened at 25 west Forty-second street. Management of the bureau is in the hands of Harry W. Perry, for the past five years associate editor of THE AUTOMOBILE and

more recently associated with H. F. Donaldson, publisher of the *Commercial Vehicle*. Connection with the latter periodical is still retained. Associated with him is Howard Greene, who for several years has been a writer on mechanical subjects on the staff of the *Horseless Age* and THE AUTOMOBILE, having concluded his connection with the latter with the close of the year. Although a specialty is to be made of automobile subjects, it is planned to furnish special articles from time to time for technical or class papers devoted to other lines.

AN IMPROVED FRENCH WINDSHIELD.

PARIS, Dec. 20.—Since its first appearance about a year ago the swinging windshield invented by M. Huillier has had immense success. Briefly, it consisted of a glass shield hinged at its upper edge to two upright side stays curved upward at their extremity, and a waterproof leather apron uniting its lower edge to the outside of the dashboard. Its disadvantage—a disadvantage common to the ordinary type of windshield—was that it could not be raised or lowered or put out of use when not required. The inventor has improved on the first model, as will be seen by the illustrations herewith. A metal upright stay is attached to each side of the dashboard, and on it slides a sector bearing a lighter stay to which the shield is hinged, and provided with a thumb-screw by which it can be retained at any desired height. By means of the sectors the shield can be placed at any distance from the driver, or when it is lowered can be maintained at any angle. A leather apron connects the lower edge of the shield with the dashboard. Fig. 1 shows the screen lowered; Fig. 2 illustrates the screen raised to a normal height. In Fig. 3 it is lowered and placed at an angle, as it would be used in heavy rain, giving the driver some protection while offering no obstruction to the view; and in Fig. 4 the screen is raised as high as possible. A further advantage of the shield is that it can be fitted on any car without special measurement, and in position 2, 3 and 4 it may be used between front and rear seats. The shield is patented.

OPINIONS CONCERNING TWO-CYCLE ENGINES

JUDGING from the varied comment elicited by the article on the two-cycle engine, by C. P. Malcolm, which has been appearing in *THE AUTOMOBILE*, it is evident that the interest in this type of motor is far more widespread than would appear to be the case to the casual observer, particularly in view of the fact that but one firm has had the courage of its convictions in this connection where the automobile is concerned. That the two-cycle motor represents the ultimate stage of the evolution of the internal combustion engine, is the firm belief of many authorities whose experience and standing entitles their opinions to considerable weight. Simplicity, with a maximum of power from a minimum of weight, must always be the aim of the designer, as it has been in the past, and there are many who incline to the opinion that the realization of this points in the direction of the perfection of the two-cycle idea and none other. There are those, however, who maintain that two-cycle operation and high speeds are incompatible with a high degree of efficiency and will never be realized in practise. Accordingly they are seeking simplicity in another direction while still retaining the four-cycle principle, in order that a more complete scavenging of the combustion chamber between strokes may be brought about and a higher degree of compression employed, both of these being universally conceded to be among the first essentials of efficient operation. This is the case of Charles E. Duryea, whose letter is appended here, as he is of the opinion that the success of the rotary valve will eliminate the necessity for further employment of the two-cycle principle.

AN EVOLUTION IN AUTO ENGINE BUILDING.

Editor *THE AUTOMOBILE*:

Since 1899 there has been a steady advance and evolution of building engines for automobile use. At that time the Otto type of engine was the accepted type for automobile service, principally because of its being a high-speed engine, which allowed of using a similar engine utilizing this high speed and then gearing back by the means of chains to the driving axle. This type of engine was used exclusively for automobiles until 1899, when the Elmore Manufacturing Company, of Clyde, O., entered the field with a motor of the two-cycle type. This type of motor was used almost exclusively for marine purposes, and was always supposed to be a motor of very limited speed; in fact, the speed was so low that it was not well adapted for automobile work, and therefore did not have much consideration. The Elmore company, however, seeing the possibilities of the two-cycle motor, decided that it could be improved so as to make it the ideal motor for the automobile.

The first two-cycle engines, in fact nearly all of them in marine use, were of the type using valves in the crankcase, or a great many engines had been made with valves in the head of the cylinder, the same as the four-cycle, but the prevailing type was the one using a check valve in the inlet to the crankcase. The Elmore company soon found that the prevailing type of motor as used for marine purposes was not at all available for automobile purposes, and they began working on the Day, or three-port system. It took considerable experimenting and time to get the engine proportioned so as to produce the results expected, but a steady advance was made until now the evolution is practically complete. For three years past the Elmore motor has been acknowledged to possess all the qualities of the perfected motor for automobile service. It has come up fully to the expectations of its builders' and gas engine experts all over the world predict that it will be the motor of the future.

History has shown that when the limit of progress in one direction is reached, further progress has come through radical departure from these lines. However, evolutions come slow, as it is hard to make a change from one system to another until it has been clearly shown that the evolutionary system is better. In the case of the two-cycle engine this has been shown to everyone who has made a study of the situation; it is only those who are prejudiced in favor of their own system who are still doubtful. The Elmore company has made further advance in the Day type of engine than anyone else. Their product of automobiles is so well and favorably known that comment is unnecessary further than to explain the difference, or rather, similarity, of their motor to the four-cycle type.

It is generally agreed among all mechanical men that simplicity is the point to be obtained. In the two-cycle motor this point has been gained, for not only does it do away with all the complicated parts of the four-cycle engine, but theoretically it doubles the power. This means that not only is the two-cycle engine a great deal more powerful than its prototype, but it is much lighter in weight, and as it does away with most of the troublesome parts of the four-cycle it is consequently more reliable, especially in the hands of the amateur, as there are absolutely no parts that are subject to wear or displacement, even after very long and very hard service.

All history has shown that every evolution in the nature of an improvement is at first ignored, and as it gathers strength and momentum is fought by those whose interests it seems to affect. This has been true of the evolution of the two-cycle. There are probably comparatively few people who know what constitutes the difference between what is called the two-stroke cycle and the four-

(Continued on first column, page 54.)

MR. MALCOLM'S ADDED EXPLANATION.

Editor *THE AUTOMOBILE*:

I noted W. Fahrenbrink's Inquiry No. 507, concerning two-cycle engines, and I think that I might be able to give some additional information that might be of considerable value to him. In designing the ports of a two-cycle engine it is necessary to have the exhaust port as much wider than the inlet port as necessary to permit all of the pressure of the exhaust to escape before the inlet port begins to open. Before the exhaust port begins to open, the burning charge is at a bright red heat, and would ignite any fresh charge that came in contact with it, but, as in compressing a charge before it is ignited, the heat of compression keeps exact pace with the degree of compression, so in discharging the ignited gases the temperature will keep exact pace with the pressure, and the exhaust gases, which were at nearly a white heat before the port began to open, will be black as they are expanded to atmospheric pressure by being discharged in the open air. If this occurs before the inlet port opens, there will be no danger of back firing into the crankcase. In a cylinder of four or five inches stroke, the inlet port should be 3-8 inch to 1-2 inch wide, and the exhaust port from 5-8 inch to 3-4 inch wide; that is, there should be 1-4 inch lead in the exhaust port.

The bottom of these ports should be on the same vertical plane as the top of the piston when it is on its lower center, and they should extend clear around the circumference of the cylinder, with about one inch bridges to separate the exhaust from the inlet port. There should be about three very thin bridges, say about 1-8 inch thick, across the inlet port, and one, about 1-2 inch wide, across the exhaust port.

The object of extending the ports clear around the cylinder is not only to get the greatest port capacity with the least possible loss of effective piston stroke, but also because that is the only way by which the exhaust gases can be effectually swept from the cylinder by the incoming charge. This construction of ports has contributed more towards making the two-cycle an efficient gas engine than any other one thing.

It is only a few years since the usual, in fact the universal practice, was to make the ports of a six-inch bore cylinder about 2 1-2 inches, or at the farthest 3 inches long, and the charge would be deflected to the inside of the cylinder and over the top and down the exhaust side, and out of the exhaust port, leaving the larger part of the exhaust gases on each side of it undisturbed in the cylinder. If you have thick bridges across the intake port, there will be arches of the exhaust gases, extending across the cylinder from each bridge to the exhaust port, that the incoming charge cannot sweep out ahead of it, because they are shielded by the bridges. It is necessary to have bridges across the ports to prevent the piston rings from springing out into the port and catching, and probably breaking, but 1-16 inch bridge will steady the rings across the port just as well as thicker ones, but 1-8 inch is about as thin as you can bore out the cylinder with and not have the edges crumbled by the cutting tool. The exhaust port bridge, or bridges, should not be so thin, as there is nothing to be gained by it, and they will get hot quicker, being exposed to the hot exhaust gases for an instant, each revolution of the engine. The exhaust port being so much wider than the intake port, the port room that thick bridges take up is not needed for port capacity, but do not put more than one 1-2 inch bridge in unless the bore is over 6 inches.

In designing two-cycle engines the usual practice is to make the crankcase compression space as small as possible in order to get as

AN EVOLUTION IN AUTO ENGINE BUILDING.

(Continued from first column, page 53.)

stroke cycle engine. The difference is in the manner of admitting gas to the combustion chamber of the engine. In the four-cycle this is accomplished by a number of very accurately finished valves, which are operated by a complicated system of cams, levers and springs. This system is subject to variation, first in the timing of the valves, on which probably no two builders agree—in fact, experimenting is going on even at this late date to determine just what timing is proper for the valves of a four-cycle engine. Even if the valves are timed right in the first place, they are subject to the variation of the valves corroding as they are exposed to the extremely hot gases of the combustion chamber, and they are also subject to variation from lost motion in levers or cams. These valves perform the service of letting the gas into the cylinders, and also let the gas out of the cylinders, so that one revolution is used for the working stroke or power of the engine, and the next revolution the engine is idle and does no work at all, therefore the four-cycle engine is working only half the time. This idle stroke is a great detriment to the four-cycle engine on account of having to carry a very heavy flywheel to keep the momentum of the engine up while it is doing no work, which, as said above, is one-half the time. As stated above, the two-cycle engine not only does away with the highly sensitive valves and their attendant mechanism, but also has no idle stroke, producing a power stroke at every revolution, even though carrying much less compression, which allows of easier starting and much smoother running, and the two-cycle, by losing this idle stroke, gains infinitely more power, with a smoothness of action that it would take double the number of cylinders of the four-cycle type to produce. This has been acknowledged by builders of the Otto type of engine by the fact that they are multiplying their cylinders in order to overcome these spasmodic impulses and the elimination of the heavy flywheel, but in multiplying the cylinders they also multiply the parts for actuating the valves.

The entire action of the four-cycle having been explained, it will be very easy for even a layman to understand the principle and advantages of the two-cycle as now explained. The piston in the two-cycle engine performs its duty just the same as the piston in a steam engine, which nearly every one understands. In its backward and forward movement it opens and closes the inlet and outlet ports for admitting the gases into the explosion chamber and for letting it out after being burned. It performs this function with an evenness and reliability that is surprising to the oldest steam engineers. As every one knows, the piston of a gas engine, as well as a steam engine, is not subject to wear or displacement, and on this account the longevity of the two-cycle engine cannot be questioned. In fact it has been repeatedly proven in hundreds of cases of actual practice that a two-cycle motor of the best make, even after very long and hard service, will show the same or more power than it did when new. Unfortunately for those who wish to design a two-cycle engine, there is no reliable data in the hands of anyone but those who have had years of experience in the practical making and marketing of this type of engine.

While the Elmore company has been eminently successful in building this type of engine, it was proven by their first experiments that faulty design will entirely nullify all the natural advantages of the two-cycle engine, and that considerable experience must be possessed by the designer to take advantage of its simplicity.

Clyde, O.

B. A. BECKER.

DISSENTS FROM MR. MALCOLM'S STATEMENT.

Editor THE AUTOMOBILE:

In Mr. Malcolm's article on the "Development of the Two-Cycle Engine, Part II," is a statement that "With the engine running at any speed the valve will not lift, so the only practical way of using this device is to place the valve in a horizontal position"—all this referring to the small momentum valve in the piston head. Where does Mr. Malcolm get his authority for this startling assertion? The combination two-and-four-cycle engines, made in this country by a Chicago concern, were fitted with momentum valves of the type which Mr. Malcolm so emphatically condemns, and, whatever troubles may have been had with their other details, trouble with these valves was not one of them. Also, in the early Daimler V-shaped gasoline engines, which gave most excellent service, piston air valves were regularly used to supply additional air for much the same reason as constitutes the excuse for the auxiliary air admission of the modern compensating carbureter. These valves were not only held by the momentum, but were also held by very stout springs, and it is not on record that there ever was any trouble with their failing to open. Some of the engines had an arrangement whereby the spring pressure was relieved mechanically at the end of the stroke, but even this was not applied to all of the engines. I would be very much interested to know what actual tests Mr. Malcolm is familiar with, as a basis for his condemnation of this type of valve, located horizontally in the top of the piston.

New York City.

ROBERT MILLER.

MR. MALCOLM'S ADDED EXPLANATION.

(Continued from second column, page 53.)

high pressure as you can, so as to move the charge into the cylinder as quickly as can be. Some even go so far as to fill up the piston as much as they can and core it out hollow, so that it has the appearance of a solid piston, with a space in it for the end of the connecting rod. I do not think this is good practice. But you need not be afraid of back-firing with ports constructed as described, no matter how much crankcase compression you may have, for the igniting heat is all out of the cylinder before there is any chance for the charge compressed in the crankcase to get into or have any communication with the cylinder.

I do not know the size nor the style of engine that he intends building, but have assumed that they were vertical cylinders, and, if they are four or five inches bore and stroke, they should be able to run at least 2,000 R. P. M. for their highest efficiency, with the ports constructed as indicated.

A very good form of deflector, though not the best, is to have it a little farther from the cylinder walls than the inlet port is wide, and about one and one-half times the width of the port high, straight up and parallel with the cylinder walls and extending around the piston the length of the inlet port, at the ends of which it turns at a right angle into the cylinder walls. This deflector should be securely fastened to the piston if not cast integral with it, and turned off with the piston. The deflector and the part of the piston above the first piston ring should be turned off 1-100 inch smaller than the bore of the cylinder, or the heat on the surface of the piston head will expand it so as to cause the piston to set fast in the cylinder until it is allowed to cool off. The edges of the deflector also may scratch the cylinder.

If you place these two cylinders vertically, and side by side, with the cranks opposite, or 180 degrees apart, you will have a perfectly balanced engine and will get as many explosive impulses as you would with four cylinders of the four-cycle type, and from 50 to 75 per cent. more power than you could get from two four-cycle cylinders of the same size. As the cylinders are nearly cut in two by the ports, the walls of the chambers surrounding them should be cast thick enough to give the necessary strength to the cylinder. To regulate the speed, it is better to throttle the intake port of the cylinder than to throttle between the crankcase admission and the carbureter, although either will do, if the inlet to the crankcase is a check valve, or anything but a third port.

C. P. MALCOLM.

MR. DURYEA ON ROTARY VALVES.

Editor THE AUTOMOBILE:

Your correspondent, Mr. Putnam, asks concerning the rotary valve exhibited by us at the New York show, and we think likely more information would be appreciated by him. We have been testing this valve as time and opportunity permitted for several seasons and have built it in two or three sizes and in several forms. We have used this valve both taper and straight, and also along in separate lengths, one for each cylinder. Our experience points to the single piece straight valve carefully made as the most simple and satisfactory form. We have run engines containing this valve until the cylinders were so dry from lack of lubrication that the engine stopped. We did this to find out whether or not the valve would give trouble. We found in each case that the valve was still in good order because it is on the underside of the cylinder, where it gets oil from the piston at every piston movement and where any oil that splashes against the cylinder head flows by gravity into the valve. Further, since the valve is on the underside it is sure to get water more free from steam bubbles than the upper walls of the cylinder, while the presence of water in the center of the valve insures that it cannot overheat. From our experience we believe that regrinding will not be necessary oftener than once per season, and that when reground and fitted with new bushings the valve will be ready for another season's use at less expense than the ordinary poppet valves can be maintained. The saving in noise, flexibility, timing trouble and adjustment is enormous, and this device, in our opinion, makes the four-cycle engine as simple as a two-cycle, while retaining the four-cycle advantages.

Reading, Pa.

C. E. DURYEA.

THE AUTO ADVANCING INTO INDIA.

Few people realize the strides automobiling has made in India within the past two years. Cars are penetrating into the far away mountain fastnesses of the northern border land. An auto recently sold to a purchaser at Newshera made the difficult trip successfully to Dargai and the Malakand Pass, which it ascended to a height of 3,000 feet, making a continuous climb of six miles. Another trip by the same car was successfully made to the mouth of the Khyber Pass.

LETTERS INTERESTING AND INSTRUCTIVE

The Merits of Steel and Cast-iron Bearings.

Editor THE AUTOMOBILE:

[527.]—What are the comparative merits of steel and cast-iron as materials for plain bearings, as compared with the bronzes and babbitt more commonly used for this purpose? I notice that many gasoline motors of high reputation have steel-bushed connecting rod eyes working on steel piston pins, while others have steel piston pins held tightly by the connecting rod and oscillated in the piston, thus giving steel to steel in the one case and steel to cast-iron in the other. If these materials can be made to wear so well under the severe duty encountered within the hot piston, not even provision for adjustment being usually made, why should they not prove equally serviceable and durable for crankpin and crankshaft bearings, besides being considerably less expensive to manufacture?

New Rochelle, N. Y.

ERNEST C. HENCKEL.

The argument usually urged in favor of bronze and babbitt plain bearings is their comparative immunity from troubles due to faulty or inadequate lubrication. This is especially true of babbitt, the best qualities of which are possessed of really remarkable "anti-friction" properties and are capable of giving some service when dry. Moreover, when run dry too long they simply melt out without injury to the expensive shaft, thus bringing about a difficulty easily corrected by a comparatively simple and inexpensive replacement. Bronze and brass are more likely to injure shafts, while with steel or cast-iron to steel, the briefest failure of the lubrication system will be followed by overheating, scoring and seizing, to the ruination of both bearing and journal. A very important advantage of babbitt is the facility with which it can be cast in place around the journal, thus producing a close fit and perfect alignment at a minimum cost. Cast-iron usually contains an immense number of minute particles of graphitic carbon, disseminated throughout its mass, which is supposed to account for its superiority to steel as a material for sliding surfaces. With the improved and almost perfectly-reliable lubricating systems now in use, there is no particular reason why steel and cast-iron bearings should not come more and more into use. They have been used with the greatest success on some of the heaviest steam engines and other machinery ever built, and are recognized as good practice in several important departments of mechanical engineering. The subject is well worth the serious consideration of practical auto builders.

The Direction of Engine Rotation.

Editor THE AUTOMOBILE:

[528.]—Though not the owner or user of a car, I am a regular reader of "The Automobile," and as such take a great interest in the industry. Recently a friend of mine and I have had an argument about the direction in which an automobile engine, gasoline, revolves. To settle this argument, we will appreciate it if you will explain in "Letters Interesting and Instructive" whether an automobile engine can run either way, and which direction, if either, is usually preferred.

THOMAS CLANCARTY.

Latrobe, Pa.

There is no possible reason why an automobile engine should not be built to run one way just as well as the other, though almost invariably they are made to run in such a direction that the starting crank must be turned in the direction of the hands of a clock to effect the starting. Automobile engines of the four-cycle internal-combustion type rarely are capable of being reversed, however, if this is the idea you have in mind. To be able to reverse, self-starting would be presupposed, and since self-starting is neither highly developed nor extensively applied, the provision of reversing cams and the other necessary adjuncts would still require cranking to produce the change in direction. A few self-starting and reversing four-cycle motors have been made, and at least one is on the market to-day, while it seems probable that more may be built in the future. Most two-cycle engines can be reversed—usually by simple manipulation of the spark while running.

An Easy One and Then a Hard One.

Editor THE AUTOMOBILE:

[529.]—Were any of the cars in the Vanderbilt race of the two-cycle type? What is the idea of such manufacturers as the Mercedes, Fiat, De Dietrich, Pope-Toledo, Locomobile, and Thomas in using chain-drive after seeing shaft-driven cars win all the cup races to date? What is the trouble with a 30-horsepower shaft-driven car with a four-cylinder, four-cycle engine, which acts as follows: The car starts off perfectly and runs nicely for about a quarter of a mile, and then, cylinder by cylinder, the motor ceases working until only one cylinder is working and then, cylinder by cylinder, begins working again? This happens repeatedly, especially when one attempts to speed the engine or in taking a grade.

Bayside, N. Y.

A SUBSCRIBER.

No cars driven by two-cycle engines have been entered in any of the three Vanderbilt Cup races. Your next question is simply enough answered by the fact that cars equipped with double-chain drive have won race after race in the great road contests of Europe, several of which have been won over greater distances and at higher average speeds than have resulted from any Vanderbilt Cup race. This makes it perfectly reasonable that the advocates of double-chain drive should consider this detail of construction no bar to success. It is very difficult, without knowing more details of your car's construction and condition, to diagnose its troubles with any degree of positiveness. Your meager description sounds like carburetor trouble of some sort, such as might occur if the fuel feed were partially obstructed in some manner, particularly if the obstruction were such as to permit the float chamber to fill slowly, after being exhausted quickly by a heavy demand for power. Why the cylinders should cut out one after another instead of all dying down together from this cause, however, unless the intake piping has most unequal leads, is beyond us, and we shall be interested to see if the ingenuity or experience of our readers may suggest some more plausible explanation than we are able to advance.

Some Mixture and Ignition Phenomena.

Editor THE AUTOMOBILE:

[530.]—Would you be so kind as to answer the following questions in your journal? I understand that an explosive mixture of gas in a motor will take time (even though it be but a trifle) to burn up entirely. It is understood that we are using perfect mixture, not too rich or too weak. A fully retarded spark takes place in the combustion chamber just as the piston is returning on its outward stroke. The full charge of gas will not be entirely burned until the piston has traveled some distance on its outward stroke, and it is not long after that the exhaust valve opens to let the burned charge out. In my idea a charge fired by a retarded spark ought to give little power and hardly any heat at all, being that the burned charge is in the cylinder but a short time. Others say that a retarded spark will create heat. Why?

An advanced spark, it is said, will run a motor cool and faster than a retarded spark. My view is this: An advanced spark will enter the cylinder combustion chamber just before the piston reaches the dead center, and therefore the entire charge would be burned up entirely just as the piston is at dead center (if sooner will cause a knock). Compression is then at its highest, the explosion is greatest, and speed highest. Why, then, doesn't a strong explosion and high speed, and besides allowing the burned gas to remain in the cylinder much longer than with a retarded spark, cause more heat than with a retarded spark? The above is my own theory, and would like to know where I am at fault.

Chicago, Ill.

LOUIS ROCCA.

You are perfectly correct in assuming that the combustion of the charge of gaseous fuel within a gasoline-engine cylinder takes time, though it is a common error to regard the combustion as much slower than it really is. With retarded ignition, as in the case you assume, the power result is small because the combustion, with consequent pressure development, takes place after the mechanical elements of the engine—the piston, connecting rod and crank—have progressed to a position that precludes utilization of the heat. But the heat is produced none the less, and

while the burned charge is in the cylinders only a short time, this simply means that it continues to burn as it passes out through the exhaust valve and on its way to the muffler. It only requires a very slight advance of the spark itself (not inconsistent with a considerable advance of the time of commutator contact) to insure completion of combustion by the time dead center is reached, but there is no reason why a knock should occur merely because of slightly greater advance, if all of the bearings are in good condition. As a matter of fact, the knock usually attributed to undue ignition advance can hardly appear until the advance is so great as nearly to stall the motor. Power may be lost, of course, as a result of less advance than this, but since all of the pressures work downward, both during the compression and explosion strokes, what would there be to occasion a pound or knock because of too early ignition in the compression stroke? It is the practical completion of combustion before the exhaust valve opens, with consequent utilization of the heat, that keeps a motor from overheating. On the other hand, the retarded combustion, with the result that the gases are in full flame as they pass through the exhaust valve, causes the troubles usually summed up in the single word "overheating."

A Simple and Efficient Lubricating System.

Editor THE AUTOMOBILE:

[531.]—In your issue of November 8 I have read with great interest the article on forced feed lubrication for motor car engines, and I inclose you full particulars and a diagram of the Napier system of lubrication, which, I think, you will agree with me, is better than

NAPIER SYSTEM OF CONSTANT OIL CIRCULATION.

any system of drip lubrication or any system of lubrication by which the skill of the operator is called into account. Since adopting it we have never yet had a case of a car having a fired bearing when in the hands of the ordinary user. This is a good deal to say, and really, unless the chauffeur was abominably stupid, I do not see how it could happen.

S. F. EDGE.

London, England.

There are no drips in connection with the Napier oiling system, and merely one oil gauge, situated on the dash. On the left side of the crankcase a small direct-acting pump A is carried, which is driven by a worm on the half-time shaft. The oil is collected by this pump through a strainer from a well in the bottom of the crankcase. The amount of oil necessary is determined by means of a Napier gauge cock, operated by means of a lever inside the bonnet. The crank chamber is filled up each morning to the correct level, that is, until oil runs out of this small gauge cock; when this is obtained, the cock is shut and the lubrication of the car is right for the day.

The oil is delivered from the pump by means of a large bore copper tube, which carries it first of all through a sight feed B on the dashboard. From the dashboard, through another large bore copper tube, it is led to the middle of the offside of the engine, where it meets a T piece, and is then carried both backwards and forwards and distributed by means of oil studs C to the four main bearings direct, and also a certain definite determined amount is fed to each of the cylinders. Between the cylinders and the crankcase there is a metal shield limiting the splash from the crank

chamber to the pistons. This shield, having a turned-up lip D, catches the oil, retains a definite quantity always in the groove formed, and delivers a portion to the bearings E and to the camshaft F.

After being used, all the oil drains into the well of the crankcase, and, after passing through a strainer, goes back to the pump. Thus a certain definite quantity is delivered continuously to each of the bearings and also to the cylinders.

It will be noticed in the plan view that at the termination of the pipes leading to the two main end bearings of the engine, there are two small oil circulation test cocks. These are merely for test purposes, to make sure occasionally that the feeds are quite free, though the pipes themselves are purposely made of large bore to obviate the possibility of stoppage. Should anything happen to the pump, which would be immediately shown by the oil gauge on the dash, all that is needed is more oil in the crank chamber, lubricating by splash until the pump can be repaired. The mechanism for oiling the "big end" is shown in section in the small diagram, where the pipe will be seen leading downwards and squirting into the small scoop, carried by the big end, marked E. The pipe leading to the camshaft is marked G. The simplicity of the system is its chief advantage. It is certainly independent of any pressure, is self-contained, does away with all drips; it starts and stops with the engine and the lubrication in every case is directly proportional to the speed of the engine.

[EDITOR'S NOTE.—This system, with slight alterations in detail, is now in use on several American cars and is found to be very simple and efficient.]

ANSWER FROM THE ELMORE STANDPOINT.

Editor THE AUTOMOBILE:

[532.]—In your issue of December 20 we note a letter and your answer to some questions on the two-cycle motor. There are, undoubtedly, good and bad two-cycle engines, just as there are good and bad four-cycle engines. We think that in general your answer to the query is all right, but we would take exceptions to some parts of it, as we believe that our knowledge on this subject is more extended than any one else's, as we have done more experimenting in the matter than any one else in the world, and we have an actual production of cars extending over six years.

The valveless, two-cycle engine is, in our opinion, the most advanced type of internal combustion engine on the market to-day. We have made engines with valves and without, and we would consider that to make a two-cycle engine with valves would be simply to throw it back in development for several years, as it would then be subject to all the inaccuracy that is peculiar to the common four-cycle type of engine.

You speak of the screen in the by-pass becoming heated so that it would cause back-firing. We wish to correct you on this point, so far as it pertains to our own type of motor. Our screen is made of two layers of perforated steel inclosing a layer of fine mesh copper wire, on which screen we have a patent. We have absolutely never known of a case of the screen becoming so hot as to ignite the gas; in fact, we can make the absolute statement that if the screen is properly placed in the by-pass of an Elmore motor it will never backfire under any conditions of weak mixture, retarded spark, or any other known cause of backfiring.

Of course, every one has not had the experience we have had with two-cycle motors, and probably a lot of the errors which are communicated to the users through the papers are unavoidable, but it is a fact that a great many of the points that are brought up against the two-cycle motor are things that we have never experienced nor even heard of in the use of our cars; in fact, they appear absurd to us.

ELMORE MANUFACTURING COMPANY.

Clyde, O.

CREDIT BELONGS TO MR. CORREJA, OF ISELIN, N. J.

Editor THE AUTOMOBILE:

[533.]—Referring to your issue of December 20, permit me to state that M. J. J. Correja, Jr., of Iselin, N. J., is the man who will donate the land necessary for the continuance of Middlesex Road at Iselin, and not the writer, as stated in the item under the caption of "A Dangerous N. J. Railroad Crossing." It has been my pleasure and aim to put on foot this project, and Mr. Correja and myself now await such energetic and effective co-operation to accomplish this as it deserves. By continuing Middlesex road and causing the Pennsylvania Railroad Company to build a bridge, the worst piece of road between New York City and Philadelphia will be made up-to-date and safe.

A. D. HYDE.

Iselin, N. J.

AN AMERICAN VIEW OF THE FRENCH SALON

By C. W. KELSEY.

DO not think that we Americans know anything about what an automobile show should be, when we compare our American shows with that at the Palais. It is a magnificent spectacle, and was visited by people of all classes and all ranks of society. It is preëminently the great spectacular show of France, and takes preference over all other shows and expositions held there, and is a much more popular institution than are our American shows. Technically, while there were not so many changes from the standard type, as at previous shows, there were a number of interesting innovations. Among these was an exhaust valve with a camshaft so arranged that it could be advanced 80 per cent. This makes it possible to use the exhaust as a brake, relieving the compression in an emergency, and making a quick stop when necessary. This, taken all in all, is one of the most noteworthy new ideas seen at the show. It was regulated by a lever conveniently located at the dash, making it possible to advance the camshaft to any degree required.

Generally speaking, the foreigners are ahead of us in metal work, but on designing I think that we are at least a very close second, and that within a few years we shall closely approximate the best foreign ideas. I was surprised to see that practically no chrome nickel steel was used in the construction of this year's models. The front axles are generally made of high-grade iron; the Lemoyne, the popular axle, being built of that metal, and a number of other prominent makers following the same lead. There seems to be a strong tendency to use silico-manganese steel in gears. This compound makes a very hard metal and a very satisfactory one, but it is not easy to make, as there has heretofore been a great deal of trouble getting the mixture uniform. This has been overcome almost entirely by the best foreign workers.

In making castings the French are far ahead of us. The more general custom in America is to cast single cylinders. The French have outgrown this condition. They have reduced the possibility

of blowholes and other imperfections to a minimum, and therefore do not feel that they are taking any large percentage of chance in casting in pairs and even in sets of four and six. This system of multiple casting is used in most of the taximeter cabs, such as those turned out by the C. G. V., Clément, Renault and other companies. I noted that most all pressed steel work was hot pressed, making it possible to press out more intricate forms of frames and parts. In one booth I noted that even pistons were hot pressed from steel. Another tendency is to increase the general use of the shaft drive. Practically all the heavy cars and 'buses are now shaft-driven.

The use of the magneto is practically universal now. Foreign constructors seem to have settled on this, and to my mind this has been attained largely by the new Gionolli magneto, which, it is claimed, cannot be burned out. This is a big improvement in magnetos and is the only one which can be used successfully for a long time, so far as I have been able to discover, on six-cylinder machines. I was told at the show that the Stevens-Duryea people had ordered this magneto to be placed in their six-cylinder cars. I met Albert Champion, of Boston, at the show, and he stated that he was the American agent for this magneto.

Some American products were considerably in evidence. Among these was the Hyatt roller-bearing, which attracted a great deal of attention and had a large crowd continuously around its booth.

Splash lubrication with oil kept at a level by a pump is apparently the up-to-date thing abroad. I saw a great number of cars thus lubricated. Another little detail noted was that cotter-pins are almost obsolete. Lock-washers now take the place of cotter-pins. These are of special construction which does not destroy the thread or jam the bolt into the hole. In ball-bearings, the full type seems to be in favor instead of the silent type, and there is a very wide use of this kind of bearing. Offsets seem to have been generally discarded after trial by nearly all the big makers.

IN THE VICINITY OF THE GRAND PALAIS DURING THE SALON D'AUTOMOBILE, DECEMBER 7-23.

There is, of course, much interest here in the question of the six-cylinder car. In inspecting the show, I found that the six-cylinder fad was on the wane. Nearly all makers who had made six-cylinder cars were at first anxious to assert this fact, and of course there were a great number of them shown. But when I began to question the heads of concerns in their booths, I found that nearly all of them asserted that they had made the six-cylinders more for the purpose of keeping up with the procession and that they had decided not to make any large number of these cars in the future. They admitted the greater flexibility of the six-cylinder engine, but found that cost of up-keep and other deterring elements overcame the possible advantages of six-cylinder cars. I went pretty thoroughly into this subject and believe that I reflect the general feeling.

I paid a visit to the C. G. V. factory and was particularly impressed with the high quality of the workmanship there. The firm will turn out about 350 cars during the coming year. I rode in one of their 20-horsepower taximeter cabs, and found it a wonder. The car seemed to me to have at least 30 horsepower and ran perfectly with very little vibration. In this connection I want to speak of the brake construction noted at the C. G. V. factory and now generally in use in Europe. This is a steel band with cast-iron blocks running on a drum of either pressed steel

CHAIN CASE ON C. G. V. SHOWN AT SALON.

or malleable iron. Indeed, malleable iron seems to be very largely used in construction. A number of pistons are now being made of this metal.

One of the most interesting trips I took was to the Clément factory. I was much impressed with the success made by Clément during the years that he has been in the bicycle and automobile manufacture. He is one of the most remarkable men in the business. He started with nothing at all in the early bicycle days, and was so poor that he had to make one bicycle and sell it before he could make another. Later, when the Clément and Humber concerns were consolidated, Clément's rise began to be meteoric, and to-day he is represented in four big French concerns, the Clément-Bayard Company, the Clément-Talbert Company, the Clément-Gladiator Company, the Clément-Serpollet Company, and an Italian Clément company, and he is credited with being the largest stockholder in the Panhard company and its controlling factor. He is also said to be one of the largest stockholders in both the Michelin and Dunlop tire concerns, and it is asserted in Paris that he controls about half of the output of other cars in France.

Clément has a model factory for machines, and the treatment of visitors is most generous. They are placed in charge of guides and taken in parties continuously through the works, which are strictly modern in every way. The factory is very large and the raw material is taken in at one end and the finished product shipped from the other. The building is in the form of a hollow quadrangle, with a large square building erected inside. The space between the outer and inner buildings is roofed over and

serves as a roadway and testing place for the cars. Here, too, the quality of the workmanship was remarkable. I noted, for instance, that almost all the grinding of valves and other parts was done under water. Mr. Clément told me that he had already bought \$4,000,000 worth of American machinery and that he was at present awaiting the shipment of \$200,000 worth more. Incidentally, he is also looking for an American shop foreman, which seems to indicate that American skill and methods are not entirely despised in France.

All Americans are much interested in the taximeter cabs, and I was not an exception. I rode in them on every occasion possible, and was much impressed with the two-cylinder vertical motors which were used, which seemed to have a great deal of power and practically no vibration. I did not see a single cab broken down or delayed in any way while I was in Paris. The chauffeurs rent these cabs, completely furnished and equipped, by the month, and all of them that I talked with stated that their cabs had paid them well for the six months or thereabouts that they had been in use. There was, however, some question in the minds of most of the drivers whether the coming period of repairs would reduce the profits enough to make it a bad investment for them. This is a question which only the next year will settle. Nevertheless, there are about 2,000 more taximeter cabs ordered for use in Paris.

CALCUTTA TO HAVE MOTOR 'BUS SERVICE.

According to a report just received from Consul-General William H. Michael, a company known as Calcutta Motors, Ltd., has just been incorporated to conduct a general motor 'bus and freight service in that city. It is believed that it will succeed in time in driving out the bullock carts and wretched "ticcagarris" that have served in an unsatisfactory way the increasing passenger and freight traffic. A Calcutta paper says: "The development in motor conveyance for goods and passengers was sure to come. The capital of the Calcutta Motors, Ltd., is to be \$400,000. A start is to be made with ten omnibuses and ten lorries. If they could add a service of motor cars for hire by time or mileage they would confer a boon upon the community."

There are many cities in India that will make a similar change, which opens a good field for American manufacturers of motor vehicles. The sight-seeing motor car has not yet been introduced in India, and the demand for such cars should increase from year to year as the stream of visitors in the cold weather increases, as it has been doing for several years.

A SWEDISH IDEA FOR OIL MOTORS.

Consul R. S. S. Bergh sends the report from Gottenborg that J. Hesselman, a civil engineer in the employ of the gas motor manufacturing firm, Aktiebolaget Diesels Motorer, at Sjöklä, Sweden, has made an invention by which a gas motor can be reversed by a device within the motor itself, when kerosene or raw oil is used for motive power. It is remarked that if this invention is all it is claimed to be, it is very important, and will open a wide field for the use of such motors as marine engines, because they are so easy to handle compared with steam engines. A number of reversing gas engines have been experimented with in this country, but so far without practical success when put into actual service.

GLOBE-GIRDLER REACHES MEXICO CITY.

Charles J. Glidden, the Napier globe-girdler, last week arrived in Mexico City, though he had the misfortune to complete the conclusion of his journey in an ordinary railroad car. Fifty miles north of the Mexican capital his famous automobile jumped the track, and as a result was more or less wrecked, so badly, in fact, that Mr. Glidden found it necessary to ship it back to the factory in England, where it will be repaired and then sent to Port Said on the Suez Canal, where its owner and party will rejoin it later in the winter.

CHICAGO'S BIG SEVENTH SHOW.

More than 300 exhibitors of cars, accessories and sundries will hold forth during the week February 2-9, inclusive, at the Chicago Automobile Show, which is the seventh annual event of the kind. This makes it not alone the largest show that has ever graced the boards in the Windy City, but in the entire country, for, considered from the point of space occupied as well as number of exhibitors, there has never been anything approaching it in magnitude. The Coliseum and the First Regiment Armory will be impressed into service, the same as last year, and though the combined buildings provide 80,000 square feet of space, which is said to be fully 25 per cent. more than that used in any show held outside of Chicago, it has not been found sufficient to meet the demands of all who wish to exhibit.

There will be 102 separate exhibits of cars, something like 190 of accessories, and eight of motorcycles, beside which 10 applications for space from makers and something like 60 from accessory manufacturers have not been acted upon, owing to the fact that they were filed too late. Some of these will probably be accommodated, thus bringing the number over the 300 mark in the aggregate. A reduction of the amount of space allotted per exhibitor together with the fact that two additional balconies will be impressed into service this year is accountable for the increase in the number of exhibitors over last.

In accordance with what has come to be recognized as standard practise, the decorative scheme will be uniform and will be entirely in the hands of the management. Ivory, black and gold will form the dominating color motif, the carpeting being dark green set off by a red border. The center of the Coliseum will be transformed into an arched colonnade extending its entire length. The supports will be massive pillars of a cream tint surmounted by arches of staff springing from a point seven feet from the floor and rising to a height of eleven feet at their center. The arches, finished in old ivory, will, in addition, be flanked by automobile motifs; to the right a touring car; to the left a racing car at high speed, while the centerpiece of the arch will consist of a circular plaque with a wide gold border, the remainder being covered with scarlet plush. The design represents the upper half of a figure of Mercury grasping a steering wheel. The staff work was designed by Henry A. Thiede, of Chicago, while the plaque is the work of A. T. Merrick, of New York. Above the arches will be the exhibitors' signs.

In order to accommodate the additional number of accessory makers, an elevated platform has been built. The pillars of the building will be completely hidden by staffwork, and standing in front of them will be staff figures representing the chauffeur and chaffeuse, 12 of each being placed alternately. The pillars will also be used to bear the sign of the exhibitor. They will be backed with purple and run vertically. In order to secure as nearly as possible an uninterrupted view of the building as a whole, a low railing finished in gold and carrying a suitable curtain will constitute the only obstruction permitted.

The same general idea will be employed in the Annex and the Armory as well as the other departments, of which there will be six in all, except that the color scheme will be different in each case. Lighting effects have received the same painstaking attention and will be on an equally elaborate scale. The present gallery of the building will disappear in the elevated platform to be erected and from the edge of the latter will depend festoons of electric lights, while beneath and above the new gallery in suitable places will be ornamental clusters of staff of large size, each bearing eight opalescent globes.

Considered in the aggregate, the plan of decoration is the most elaborate ever undertaken in connection with an exhibition of this nature, so that the amount of labor and material its execution involves is of interest. To cover the floors 12,500 yards of carpet are required, while 120,000 square feet of material is necessary for the overhead decorations, and the building of the gallery calls for the laying of 20,000 feet of flooring. Add to this the amount of wall covering and the tons of plaster required for the staff work, and some idea of the magnitude of the undertaking may

be gained. To complicate the problem everything must be installed within 24 hours after the building comes into the possession of the show management. Consequently everything has to be in readiness to put in place, so that the work of preparing the decorations was begun two months in advance. One hundred men have been employed constantly for that period and 300 will be necessary to install the decorations. To accommodate the completed material during the interim, four stores, a loft and a basement were needed. The total cost of the work is estimated in the neighborhood of \$30,000, but this represents a saving to the industry as a whole of something like \$50,000, as under the old method every firm had to send men in advance to contract for signs, decorations and furniture, whereas now the exhibitor is called upon to do nothing more than put his cars in place.

The benefit to be derived by Chicago from the holding of such a show is also an item of interest. It is estimated that the exhibitors and their employees will number at least 2,000, while visiting dealers will account for a like number. How many prospective purchasers will visit Chicago from the surrounding country solely for the purpose of attending the show is a question that it is impossible to answer definitely, but it is thought 20,000 is not an excessive estimate. For instance, Denver, Col., will send a special delegation of dealers in three sleepers; Canadian dealers are expected to be on hand in force, and the chief dealer of Havana, Cuba, will send a representative, showing that interest is not confined to local firms by any means.

PITTSBURG TO HAVE AN APRIL SHOW.

PITTSBURG, PA., Jan. 7.—The Automobile Dealers' Association of Pittsburg is at work even now on its April 7-13 show, and the representative of every car sold in the city except one is involved in the enterprise. Herewith are the fifteen concerns which compose the association: Standard Automobile Company, Bankers Bros., Atlas Automobile Company, Fort Pitt Automobile Company, East Liberty Automobile Company, Hiland Automobile Company, Keystone Automobile Company, Winton Motor Carriage Company, Allegheny Automobile Company, Auto Repair Company, Central Automobile Company, James Motor Company, Wilkinsburg Auto Garage Company, Liberty Automobile Company, Colonial Automobile Company.

Almost every American manufacturer of prominence, whose cars have sufficient power for hilly country, is at present represented in Pittsburg—there being 56 makes, comprising over 100 models. Owing to hilly country and bad roads, automobiles, to give satisfaction in and around Pittsburg, are required to have more power, have better brakes and be better constructed than those sent into any other large city in the United States. The Pittsburg dealers realize this; hence nothing but reliable, powerful cars are handled here. At the present time there are more high-priced, high-powered cars in Pittsburg in proportion to the population than anywhere else in the United States.

The Duquesne Garden is specially adapted for holding an automobile show, the entire space being on one floor, without the view being obstructed by any pillars or partitions. Within a circle of 75 miles of Duquesne Garden there is more of a population than any similar circle drawn about any city in the United States, excepting New York and Chicago. This district, drawing from West Virginia, eastern Ohio and western Pennsylvania, is, as far as mills, mines, etc., are concerned, the most prosperous in the United States. The workmen, as a whole, receive larger wages and steadier employment than any other locality in the United States, and there is more money paid in wages in this field than any other space of the same size in the world. It is estimated that there will be \$3,000,000 expended for new automobiles in the Pittsburg district in 1907.

This is Pittsburg's first automobile show, and will cost the dealers in the neighborhood of \$50,000. The show committee, which is composed of W. H. LaFountain, Earl Kiser, Thos. I. Cochran and W. N. Murray, state that the whole of the automobile space has been sold and nearly all of the sundry spaces.

THE FARMER AND THE AUTO, TO-DAY

BY A. R. PARDINGTON, SECOND VICE-PRESIDENT LONG ISLAND MOTOR PARKWAY, INC.

BUT what of the farmer in this new era, the age of automobiles, this period of rapid transportation? Did anyone ever hear of the farmer—our one class of nobility—being left by the roadside? Never. For years now we have heard of bankers, insurance magnates, railroad investors, lawyers, and numerous other classes as being addicted to the use of the automobile. Due to the narrow-mindedness of a few, the farmer has been presented in the light of an obstructionist, an opponent of good roads, and as one who gloried in blocking the wheels of progress as exemplified by the automobile. But his attitude had some reason.

Why the Farmer Was Prejudiced at the Outset.

The early antagonism of the farmer was influenced by a very small number of the extremely thoughtless, very rich, who burned up the highways, left a trail of dead domestic animals and fowls, and the "women folks" all aquiver with their last hairbreadth escape. These very few thoughtless automobilists had been accustomed to autoing abroad, where the rural population had been through years of just such experiences, and where draft and pleasure beasts had long since become accustomed to the strange sounds and weird sights. Popular sentiment against the automobile and the automobilist was quickly aroused, and, judging from the press reports which were read daily, was soon at fever heat. Other automobilists came, driving other cars. They were of a different class, showing consideration for other users of the highway—even going so far as to stop their motors and assist the farmer to drive his beast, by leading, and by a kindly word spoken. Others, who had driven high-spirited horses—realizing the effect of the human voice—spoke to the animals as they slowly passed. There were still others, and to them belongs much credit for the quick eradication of the adverse sentiment. These, when they came up with a horse which displayed fear, stopped and urged the driver to then and there educate the horse to the presence of the automobile.

Good Work Done by the Thoughtful Autoist.

To the really fine work done by this class of autoists is due the real credit for the generally cordial relations which now exist between the non-autoing farmer and the autoist. To this class also belongs much credit for the increasing number of cars owned and operated by farmers. At these words, I hear an audible smile from some of my readers. If you do smile, and are inclined to doubt the truth of my statement, I say that I can tell you where you do not live. You do not live on Long Island, nor in certain parts of New Jersey, nor in a section of Massachusetts, nor even in good old Indiana, for the automobile-owning farmer is no rarity there, nor is he in thousands of sections of the country, where enlightenment prevails or where proper conditions obtain.

The schooling of the farmer has been rapid, but thorough. He is not likely to unlearn anything that he has learned. He has taken to the automobile with the same avidity as to the telephone. The telephone helped him to lift himself by his boot straps out of his seclusion and retirement. It broadened his view of life. It enriched his pocket. He made his sales at the high peak, and his purchases on the down sweep of the curve. He learned the weather reports before his city neighbor did. He set his watch each day on a signal from the naval observatory at Washington. He followed the progress of the world of events and was independent. Then came the automobile. His first acquaintance with it was disastrous. He watched it fly down the road, followed by a cloud of dust, and from the wreckage he dug up his pet dog—dead. He sought further and found a blooded "Rock" or "Cochin"—also dead. The cloud of dust that followed the automobile was followed by a flow of "langwidge" and of such character that its repetition would blast. Later there came

another automobile, going much slower and blowing no horns. This time our farmer friend and his wife were about to drive on to the highway, on the way to "town." The horses were quickly reined in, and the ears of the good wife were shocked at the expletive which escaped our friend's lips. Slower and slower came the automobile until it stopped short of the driveway. Its driver beckoned to the farmer to proceed, but was met by a shake of the head and "some few words." The motor is stopped, and its driver leaves the car and salutes our friend in an easy manner, with the result that an hour is lost, but a firm exponent of the automobile is found. The horse has been educated. He has even put his nose into the tonneau and forgets to scare when the car moves. There are two other horses in the barn, which are also educated. There is a converted farmer, but a doubting housewife. A ride to "village," only two miles away, and a speedy return, completes her conversion, and there you are. The result? That farmer owns a good second-hand car in which he does his "errands." His wife is taken to the sewing circle or the Ladies' Aid, and how the tongues do buzz. She hears discredit, sarcasm, unbelief, and gossip. She replies by inviting her neighbor to ride home with her when the husband comes. Another convert and another car. The first link in the chain was forged only three years ago. Already it extends half way across the Continent.

Autoing Agriculturist Is an Accomplished Fact.

An isolated case, you say? By no means; on Long Island, where I live, it is common, and is becoming more common day by day. A short time ago this conversation was overheard on a Long Island Railroad train. The writer had been in attendance upon the annual Farmers' "Institute," and was returning to the city. Seated across the aisle was a well-known Long Island farmer, one of the up-to-date kind, a representative citizen. One of those who had attended the institute entered and dropped into the seat alongside of the delegate. "Well, Charley, did your folks go into the city this winter?" "No, we stayed on the farm. We bought an automobile, and the winter has been so open that we have used it a lot." From this point the conversation lost interest, but it proved the fact that the farmer is taking to automobiles. One farmer, living in Nassau county, Long Island, who two years ago fought the proposition to hold the first race for the William K. Vanderbilt, Jr., cup on the county highways, now owns an automobile, his son owns one, and together they secured signatures to a petition to have the event held on those roads for the third time. In his arguments with his neighbors he tells them that within ten years they will be hauling their produce to market in motor trucks.

Yes, the farmer is taking to the automobile, and justly so. It has enhanced the value of his acreage; it has annihilated distances, and made every resident of his county his neighbor; it has made his farm a suburban holding and has put him into the closest possible touch with the outside world.

Commercial Importance of the Farmers' Support.

Out in Indiana, one automobile concern has a salesman, whose sole duty is to interest the farmer. Sales are an every-day occurrence, each one stimulating others. In Minnesota, due to the phenomenally successful season of 1905, hundreds of farmers, who already owned pianos, are now buying automobiles. On Long Island the automobile-owning farmer has come to be a factor to be reckoned with, particularly when good roads are opposed by the non-progressive class, who are "agin" everything that makes for the betterment of general conditions.

The logical sequence of this move on the part of the farmer will undoubtedly be the motor plow, harvester, thresher, pump, corn sheller, and in time the independent electric light installation for the house and the barn.

CLUBS BUSY OUTLINING SEASON'S WORK

Lack of Discrimination by Oakland's Police.

OAKLAND, CAL., Jan. 3.—Local automobilists, and those of San Francisco as well, are much interested in the outcome of the protest which has been filed by the Automobile Club of California with the city authorities against the abuse of official power by its police officers. L. P. Lowe, chairman of the club's executive committee, has addressed an official letter to the mayor of the city, asking that the matter be taken under advisement with a view of remedying the annoyances to which law-observing automobilists are subjected. From complaints received at club headquarters it appears that no distinction is made between drivers who are trying to observe the law and drivers who are running at all rates of speed, and practically every one has been stopped and detained at the pleasure of over-zealous officers, to the great annoyance of the feminine members of touring parties especially.

In his letter to the mayor, Mr. Lowe tersely expresses the autoists' side of the matter as follows: "As against arrests of the wilful transgressors, officers should be instructed to consider both time and place and not make arrests for mere technical violations of a speed law, as if highway users, driving no matter what kind of a vehicle, be timed over a measured distance, it is safe to say that the very great majority of them will be found to be exceeding the legal rate of speed. This is pronouncedly so in the cases of electric cars, and noticeably so with milk and bread wagons, express teams, baggage wagons, delivery wagons, etc., which must necessarily be driven with rapidity if their business is to be attended to in the time limit at their command. While drivers of automobiles are certainly amenable to the law, it must be borne in mind that so also are all other highway users, and automobiles should not, therefore, as a class, necessarily be selected for prosecution or persecution. They might, in justice to themselves, retaliate by causing the arrest of all classes of technical violators of speed laws, but if this were done the courts would be so overcrowded that these cases alone could not be heard for very lack of time. Automobilists, however, have no desire to protect themselves by such extreme and unfriendly measures, and merely ask that they be afforded fair and liberal treatment, which, I am sure, you personally feel is their due."

Preparations for New Jersey Endurance Run.

NEWARK, N. J., Jan. 7.—As it has been definitely decided that the New Jersey Automobile and Motor Club will hold a 500-mile endurance run in the spring, the club officials are gathering such advance information and statistics of other contests as will enable them to formulate conditions and rules for the government of the run that will give every competitive car an equal chance in its class. Secretary H. A. Bonnell has been gathering a volume of necessary data for the use of the committee which will prove of great value in its deliberations. The committee realizes that for the contest to be a success its rules must be stringent enough to provide that the cars not only cover the distance without need of repairs, but also cover it within a certain fixed time. The cars will, in all probability, not be required to appear at the checking stations exactly upon a certain minute, as was the case in the Glidden tour, but will be allowed some slight leeway. Most of the dealers who would enter and who, as club members, have been consulted upon the matter, have expressed the opinion that to allow a half hour deviation from the time set would be fair to all the contestants. Under this plan all the contestants would have to appear to be checked in not later than schedule time, but would be allowed to appear at the stations 30 minutes in advance of schedule time if they preferred. If the cars checked in either earlier or later than within this half-hour period they would be penalized according to the magnitude of the offense. Observers are now being chosen for the run.

St. Louis, October 19, for the Balloon Race.

October 19 is the probable date and St. Louis will be the place for the start of the International Cup balloon race. President Cortlandt Field Bishop, Alan R. Hawley, J. C. McCoy, Augustus Post, and Leo Stevens were the members of the Aero Club of America who investigated the advantages in St. Louis and reported favorably to the board of directors, which has unanimously decided in favor of the Missouri metropolis. In the announcement by President Bishop the following is contained:

"As has been previously intimated, St. Louis is, from a geographical point of view, exceptionally located, being far removed from the sea in all directions. The city authorities have set apart for the starting point a portion of Forest Park. This place can be inclosed in such a way that there will be no interference with the inflation of the balloons, and the supply of gas will be sufficient for quickly inflating any number of balloons.

The club proposes to hold the contest during the period of full moon in the month of October—probably on October 19. According to the information obtained by the weather bureau during a long period of observations with kites and pilot balloons, the usual wind prevailing at that season of the year in the upper altitudes proceeds in an easterly direction towards New York, avoiding the Great Lakes, going to the south of them. Fine weather is invariably to be expected, there being usually but three or four days of rain in the month of October. It will be recalled that the greatest known balloon flight ever made in the United States was made from St. Louis by John Wise in 1859. He landed in Jefferson county, New York State.

"The Aero Club of America is enabled to announce that gas will be furnished free of cost to all contestants for the International Aeronautic Cup. Special rates will be secured at the hotels, and if a sufficient number of members of the clubs belonging to the International Federation attend, it will be possible to secure a special rate of fare from New York to St. Louis and return.

"Besides the prizes annually offered in the International Aeronautic Cup contest, various organizations of St. Louis will offer supplementary prizes for second, third and fourth places, amounting altogether to about 5,000 francs. For those wishing to make trial flights in preparation for the International Cup contest, or for those wishing to compete for the "Lahm Cup," which will be offered for competition by the Aero Club of America, after March 1, 1907, arrangements have been made to supply gas at a specially reduced rate. This applies only to pilots recommended by the Aero Club of America. The rules of competition for the Lahm Cup will be announced later. Contestants will be afforded every facility by the gas company at St. Louis.

"You are reminded that under the conditions, entries for the 1907 contest for the International Aeronautic Cup close on February 1, 1907."

Ohio State Automobile Association Meets in February.

CLEVELAND, O., Jan. 7.—A meeting of the Ohio State Automobile Association will undoubtedly be held here during the auto show week in February. It is proposed to organize a movement which will extend over the entire State, for the betterment of road conditions. Automobile clubs are being organized in all the leading centers, and the doctrine of good roads will be disseminated thoroughly during the next few months by the organizations that are already established and have a sound and stable footing. The recently reorganized club at Akron has been incorporated, and the automobilists of Elyria are preparing to form a local organization. A Cleveland man may be elected secretary of the State organization at its meeting, and if this is done Cleveland will become the center of the movement for the Buckeye State. Already the farmers' journals of Ohio are advocating improved highways, and their support, it is believed, can be

counted upon for any reasonable system of road building that may be submitted to the next Legislature.

Plans for the sample of modern highway which will be built by the Cleveland Automobile Club between Euclid and the Lake county line, in the direction of Painesville, indicate that nothing in the nature of brick paving will be considered. Secretary Goddard is authority for the statement that the road will be built of macadam or something as good. The plans include a foundation which may be used in the future as a basis for paving if desired.

President Cobe Advocates More Liberal Auto Law.

CHICAGO, Jan. 7.—President Ira M. Cobe, of the Chicago Automobile Club, states that the present year promises to be one of great importance to the automobilists of Illinois, because State regulation through the medium of legislative enactment is practically certain to come. Last year a bill that was satisfactory to autoists passed both legislative houses, but was vetoed by the Governor. A strenuous attempt will be made this year by the Chicago Automobile Club to secure the passage of a similar act, with such changes as will meet the objections raised by the Governor to the former bill.

Standing Committees of the Long Island Automobile Club.

BROOKLYN, N. Y., Jan. 7.—Standing committees of the Long Island Automobile Club were announced at the last meeting of the club, the chairmen for which are as follows: Law and legislation, Col. James D. Bell; technical, Louis T. Weiss; good roads, A. R. Pardington; runs and tours, Charles Jerome Edwards; garage, A. C. Howe; entertainment, Edwin Melvin; membership, C. H. Galt; finance, Alfred Wilmarth. The first of the new year's exhibition nights takes place Friday, January 25, when talks will be given on the Ford, Thomas, and Stevens-Duryea cars.

Elsie Janis Joins the Worcester Club.

WORCESTER, MASS., Jan. 7.—The board of governors of the Worcester Automobile Club last week made Elsie Janis, the youthful star of "The Vanderbilt Cup," an honorary member of the club, after tendering her a reception and banquet.

CLUB DOINGS IN GENERAL.

PHILADELPHIA.—The first general meeting of the Quaker City Motor Club since its incorporation will be held at its quarters in the Hotel Majestic, February 7. At this meeting permanent officers will be elected.

AKRON, O.—The Akron Automobile Club has been incorporated by F. W. Work, S. G. Rogers, Fred C. Wood, A. H. Marks, and N. O. Mather, all prominent automobilists of this city. At the next meeting of the club permanent officers will be elected.

GUADALAJARA, MEX.—Governor Miguel Ahumada, of the province of Jalisco, has been invited as the guest of honor to the banquet of the Automobile Club of Guadalajara, which will be held the latter part of this month, in the Cedral park, at the Escoba cotton factory.

BUFFALO.—A large delegation of members of the Automobile Club of Buffalo will take advantage of the special transportation rates granted the club to visit the Madison Square Garden automobile show next week. Secretary Lewis is making the necessary arrangements for special accommodations.

CHICAGO.—At the annual meeting of the Chicago Motorcycle Club the following officers were elected for the ensuing year: President, S. W. Fahrney; vice-president, Grant W. Hunter; recording secretary, C. H. Lamb; financial secretary, C. W. Van Sickle; treasurer, E. W. Keller; captain, W. L. Johnson.

THE AUTOMOBILE CALENDAR AMERICAN.

Shows.

- Jan. 12-19.....—Annual Automobile Show of the Association of Licensed Automobile Manufacturers, Madison Square Garden, New York City.
- Jan. 19-26.....—Baltimore (Md.) Automobile Show of the Automobile Club of Maryland and Dealers' Association.
- Jan. 21-23.....—Los Angeles, Cal., Morley's Rink, First Automobile Show of the Automobile Dealers' Association of Southern California.
- Jan. 28-Feb. 2.....—Washington (D. C.) Automobile Show, Dupont Garage, Washington Automobile Dealers' Association.
- Feb. 2-9.....—Chicago Automobile Show, Coliseum and First Regiment Armory. S. A. Miles, manager, 7 E. 42d Street, New York City.
- Feb. 11-16.....—Detroit, Mich., Sixth Annual Automobile Show, Light Guard Armory, Tri-State Automobile and Sporting Goods Association. E. E. Mc Masters, manager.
- Feb. 18-23.....—Fifth Annual Automobile Show, Buffalo, Convention Hall. D. H. Lewis, manager, Teck Building.
- Feb. 25-Mar. 2.....—Portland, Me., Second Annual Automobile and Power Boat Show, The Auditorium.
- March 2-9.....—Chicago, Second Annual Power Boat Show, Seventh Regiment Armory. W. C. Andrews, manager, 19 E. Huron street.
- March 4-10.....—Kansas City, Mo., First Annual Automobile Show, Convention Hall. Frank L. Woodward, manager, Willis Wood Theatre Building.
- March 18-23.....—Providence (R. I.) Automobile and Power Boat Show, Infantry Hall. F. M. Prescott, manager.
- April 6-13.....—Montreal, Canada, Second International Automobile and Sportsman's Exhibition. R. M. Jaffray, manager, 309 W. Notre Dame street.
- April 8-13.....—Pittsburg, Pa., First Annual Show of the Pittsburg Automobile Dealers' Association, Duquesne Garden.

Race Meets, Hill Climbs, etc.

- Jan. 22-26.....—Ormond-Daytona (Florida) International Race Meet, Florida East Coast Automobile Association.

Motor Boat Races.

- Jan. 29-Feb. 1.....—Palm Beach, Fla., Annual Races of the Palm Beach Power Boat Association.
- June 8.....—670-Mile Ocean Motor Boat Race, New York to Bermuda. Motor Boat Club of America and Royal Bermuda Yacht Club.
- Sept. 2-6.....—Jamestown (Va.) Exposition, Motor Boat Races.

FOREIGN.

Shows.

- Jan. 5-12.....—Dublin Motor Show, Irish Automobile Club.
- Jan. 18-26.....—Birmingham (Eng.) Automobile Show.
- Jan. 25-Feb. 2.....—Liverpool Motor Show, Tournament Hall.
- Feb. 1-9.....—London, Crystal Palace Motor Show.
- Feb. 16.....—Automobile Exhibition at Turin, Italy.
- March 7-16.....—London, Olympia Commercial Vehicle and Motor Boat Show.
- April 6-13.....—London, Agricultural Hall Motor Show.
- May 1-15.....—Madrid, Spain, Automobile Exhibition, Palace of Fine Arts, Royal Automobile Club of Madrid.
- May 15-26.....—Third Annual Swiss Automobile and Cycle Show, Zurich.

Race Meets, Hill Climbs, etc.

- Feb. 23-27.....—Voiturette Contest, Automobile Club of Italy.
- March 20-27.....—Nice (France) Automobile Week.
- April 1-15.....—Spring Wheel Competition.
- April 21.....—Targa Florio Tour (Sicily), Auto Club of Milan.
- April 25-28.....—Touring Contest, Automobile Club of Touraine.
- April 28.....—Chateau Thierry Hill Climb.
- May 1-15.....—Paris-Madrid Touring Competition.
- May 29-June 1.....—Irish Automobile Club Reliability Trials.
- June 3-12.....—Herkomer Cup, Automobile Club of Bavaria.
- June 14.....—German Emperor's Cup, Taunus Circuit, Imperial Automobile Club.
- June 24-29.....—Scottish Reliability Trial, Scottish Automobile Club.
- Aug. 11-20.....—Coupe d'Auvergues, France.

RECENT TYPE OF ENGLISH ARMORED CAR.

GERMAN WAR AUTO SHOWN AT BERLIN.

AUTOS FOR THE SWORD AND PLOUGHSHARE.

During the past two years automobile shows abroad have held a potent attraction for that portion of the public that merely comes to look and wonder, to whom all ordinary automobiles look pretty much alike, and to whom an object of more than passing interest must possess unusual and bizarre features. These have been supplied by the exhibition of armored cars at the recent Berlin Show and Paris Salon, and by the agricultural implements designed to be operated by gasoline motors that have become a feature of the annual display at Olympia in London.

Anyone who has watched the rapid flight of an ordinary touring car over a dusty country road can picture to himself what that might be converted into were the car one of the armored vehicles that forms the *piece de resistance* of some of the maker's stands. Instead of the peaceful carload of autoists intent upon nothing more serious than breaking the local speed regulations, one of these oddly-shaped vehicles would come rushing along with no visible sign of human control or guiding hand steering it on its course. The all-enveloping cloud of dust would be supplemented by the smoke from the rapid discharges of the quick-firing rifle

mounted in the turret-like hood over the rear of the car, and this, combined with the flashes of flame shooting from the surrounding haze that marked the swift progress of the vehicle, would make the sight of one of these cars in action something long to be remembered. To come back to them, peacefully standing inert at the maker's booth, they are objects of curiosity that lead the interested visitor to poke his head into the driver's compartment and the turret, feel the armor, mentally calculating its thickness and ability to withstand projectiles and the like.

The agricultural development of the automobile motor, on the other hand, introduces a flavor of the county fair to the show. The presence of plows, harrows and reapers, though they are merely auxiliary to the motor vehicle that is to drag them in operation, is more suggestive of the local aggregation of prize-winning pumpkins and swine than it is of high-priced automobiles. But not alone their novelty and the seeming inappropriateness of their surroundings serve to make these agricultural automobiles of absorbing interest, but likewise the excellent records they have made in actual service during the past two years. They have demonstrated that they are the equal of a far greater number of horses than could be employed economically.

MOTOR-DRIVEN PLOW THAT HAS BEEN SUCCESSFULLY INTRODUCED IN GREAT BRITAIN.

The Seventh Madison Square Garden Show. Though second in time of occurrence so far as the present show season is concerned, the exhibition of cars that will be thrown open to the public next Saturday night is first in importance for a number of reasons.

Foremost among these is the fact that, with but a very few exceptions, the ranks of the exhibitors are made up of men who have been identified with the industry in this country since its very inception. They are those who have borne the brunt of the long period of the earliest stages of development of the automobile on this side of the Atlantic—a period when the business of automobile building was in a chaotic state, when experience came high and the rewards were meager. Success was largely a comparative term, for the successful car of one year gave way to something different before the end of that same twelvemonth, the frequent necessity for totally abandoning what had only been developed after a great deal of thought, labor and expense being but one of the numerous disappointments with which these pioneers had to contend during their long term of apprenticeship.

The cars that will be staged in Madison Square Garden during the coming week are the successors of many generations of American machines that have gone before, and as such they may well be said to represent most closely the trend of American thought in automobile design and building. A composite of the aggregate can doubtless be taken as the standard American automobile, in that such a car would be truly representative of the most advanced design recognized in this country, as well as embodying the best materials procurable anywhere. Whether taken singly, or as a whole, they stand second to none in any

of the qualities that go toward making the perfect automobile, insofar as that qualification may be applied to anything human, and, more particularly, they not alone compare favorably, but can now hold their own with the finest productions from abroad.

If France levied an import duty equal to that in force here, an American car would cost as much in Paris as a French one does in New York—a fact that may be readily confirmed by noting the prices at which the French productions are sold in England. As there will be a representative exhibit of imported cars at the Garden, the show will afford an opportunity for comparison and will demonstrate that the American car is second to none.

Nevertheless, High-powered Runabouts Will Sell.

When a man gets into the habit of dwelling upon a subject that he dislikes, his aversion to it grows unconsciously; sooner or later it develops into a settled prejudice, and the latter is stimulated merely by thinking of it; his jaundiced eye can see nothing but the objectionable traits in everything it regards, and in the end he becomes wholly dominated by his dislike—by an idea. Generally speaking, his type of self-propagated and self-nurtured dislike is the result of neither fact nor reason; it is the outcome of what may best be termed mental strabismus, and the prejudiced critic who has thus set himself apart, on a pedestal as it were, finds it impossible to view things as do others.

Automobile racing has been the *bête noir* of the publisher of the *Horseless Age* ever since the inception of the sport. He has inveighed against it from afar and decried it at close range; he has called the gods to witness its utter folly and absolute inanity on every occasion, and every accident or fatality attendant upon an event of the kind has been made the subject of a voluminous “I told you so.” He cannot see any possible way in which the industry can be benefited by it; on the contrary, every racing event held is but one more setback. Racing is doing positive harm to the automobile builder and his interests, from whatever point they may be regarded. Consequently, everything pertaining to racing comes under the ban of his exceeding disapproval, and the latest to be placed in this category is the high-powered runabout. Its very appearance is suggestive of nothing but racing, and its high power makes it fit for nothing else whatever, are his conclusions. Hence, should it be banished forthwith.

In the same issue it is mentioned, in the course of an editorial, that “the easiest riding position upon a car is as nearly as possible half way between the rear and front axles.” Yet the fact that that is exactly where the seats of the high-powered runabout are placed, and that possibly comfort may be one of the *raison d’être* of that type of car, never seems to have dawned upon the authority in question. That there are autoists galore who prefer not to be compelled to travel about with several hundred pounds of empty tonneau capable of accommodating four or five passengers, is another fact that seems to have escaped him. There are others besides, but the fact that the runabout looks racy overshadows them. What else can it be but a racing demon—?

Captious Criticism That Misses the Mark.

The *Engineering Record*, in a recent two-column leading editorial, discourses on “The Automobile for Engineering Purposes,” and in the article mingles touring car, motor truck and poor roads in a rather interesting manner. After condemning the upholstery of the touring car and criticising its lack of baggage space, the writer concludes that “a bad dirt road is not the place for the present standard low-powered truck.” We think a bad road is not a good place for a horse or a mule, and not even good for walking. As to “standard low-powered trucks,” our engineering friend should recall that motor trucks are not possibly of standard equipment, but must be constructed for the special service required and all engineering necessities complied with at the same time. When this is done, the automobile will show a marked economy over horse-drawn vehicles of any kind.

ASA GODDARD'S RESULTFUL OHIO ACTIVITY.

CLEVELAND, O., Jan. 7.—The Cleveland Club is making every effort to awaken new interest in automobile matters throughout the State, and it is doing this by assisting in the formation of automobile clubs and the rejuvenation of those which have become inactive. Last week Secretary Asa Goddard went to Akron and assisted in the reorganization of the club in that city, and this week Mr. Goddard went to Elyria, where a promising club is in course of organization. The aim is to form a circuit of good, live local organizations throughout the State, so that the Ohio State Automobile Association may amount to something in the advancement of the cause of good roads, and be in a position to effectively resist the enactment of unjust laws discriminating against automobiles.

While the social features of the local organizations are talked of to a great extent, the primary idea of the local club is to place the automobilists of the State in a position to put up a strong front by the time of the next legislature, so that a suitable appropriation may be secured for good roads work and a State good roads commission, similar to those in authority in eastern States, brought about. Another piece of legislation which the Cleveland automobilists have in mind is securing better regulations relative to the registration of automobiles. As the statutes now stand, an automobile party going from one State to another, and even traveling in this State exclusively, is subjected to a great number of annoyances. Licenses issued in one State are not recognized in another State. It is hoped that a universal recognition of licenses can be obtained in Ohio, as has been done in some other States.

Secretary Goddard is being boomed for the secretaryship of the Ohio State association. Mr. Goddard has a national reputation as an automobile worker, and he has accomplished a lot of good since he assumed his present duties in Cleveland. This city will doubtless be selected as the headquarters of the State organization this year, so that Mr. Goddard could easily combine the duties of both offices.

A. C. OF SYRACUSE NOMINATES OFFICERS.

SYRACUSE, N. Y., Jan. 7.—Hurlburt W. Smith has been selected for the office of president of the Automobile Club of Syracuse by the nominating committee, and as his associates the following have been nominated for the official roster: First vice-president, Christopher C. Bradley, Jr.; second vice-president, Harry C. Pierce; secretary and treasurer, Forman Wilkinson. The retiring president, Willet H. Brown, succeeded the club's first president, T. D. Wilkin, upon the death of the latter, and has held the office ever since. It is expected the nominations will receive the unanimous consent of the annual meeting of the club to be held shortly, and at which a buffet lunch will be served and social plans perfected for the balance of the winter season.

Plans are being made for the annual banquet of the club in February, when several speakers prominent in the automobile world will be present. A busy year is expected in club matters, and it is hoped to increase the membership from its present number of 150 to over 200. Fifty members were admitted during the past year. Good roads will still be the war cry of the club for next season, and the good work of placing signboards along the roads, so well begun last year, will be continued.

TRYING OUT THE GALVESTON BEACH.

During the recent visit of "The Vanderbilt Cup" Company No. 2 to Galveston, Tex., Eddie "Cannon" Bald, driver of the 90-horsepower Pope-Toledo racer, and A. E. Webb, the pilot of the 110-horsepower Premier, tried out the beach course whereon Col. E. H. R. Green made a Pope-Toledo mile in 56 seconds a couple of years ago. Bald sent his Pope-Toledo a mile in 52 seconds. Webb was detained, and his Premier was entrusted to R. Reynolds, whose unfamiliarity with it prevented a fast mile.

BRIDGING FOR THE NEXT A. A. A. TOUR.

One of the difficulties encountered on the run from Hagerstown, Md., to Staunton, Va., while a path was being sought by Augustus Post for a possible route for next year's A. A. A. tour, was the necessity of fording the Opegnon river between Berryville and Winchester, Va. In order to remove this obstacle and make the route more attractive, and so influence the A. A. A. to run next year's Glidden Tour to the Jamestown Exposition at Norfolk, Virginians have striven to prevail upon the Turnpike company to build a bridge over this stream. The company is composed of anti-automobilists of the rankest type and flatly refused any encouragement whatever. Its attitude changed when it was brought out that its original charter compelled it to "bridge all streams," and, since it had evaded the stipulations of the charter for many years, the local men made it pretty warm for the company. A contract has now been let for a \$4,000 bridge, and the contractor is under bond to have it ready and open for travel by May 15, 1907. The ground is now broken and the work under way; the structure is to be of steel with concrete supports and approaches. All this shows how the advancing army of automobilists forces betterment in local conditions.

PROGRESS ON LONG ISLAND PARKWAY.

With President W. K. Vanderbilt, Jr., of the Long Island Motor Parkway in Europe, the greater part of the work in the construction of this much-wanted and much-talked-of automobile road has devolved upon General Manager A. R. Pardington and Treasurer Jefferson deMont Thompson. These two are more than busy, and recently had a satisfactory meeting with the local board of trade of Riverhead, Long Island. A substantial grant of land will probably follow from the Riverhead end of the route. Rights of way are gradually being obtained and generous additions to the subscription list are coming to hand. While it will require some extraordinary efforts to get the parkway finished in time for the Vanderbilt Cup race of next fall, the directors are confident that there will be no difficulty in being ready. The completion of the Long Island parkway will mean the beginning of other similar roadways, several of which have been mentioned in print. For the present, however, all possible effort will be concentrated upon the Long Island road, the success of which is assured beyond question.

OFFICERS FOR THE A. C. OF WASHINGTON.

WASHINGTON, D. C., Jan. 7.—The Automobile Club of Washington has elected the following officers for the ensuing year: President, Robert B. Caverly; vice-president, Col. C. E. Wood; secretary, Leroy Mark; treasurer, O. J. De Moll; captain, Frank H. Edmonds; lieutenant, C. Royce Hough. In retiring from the office of president, W. S. Duvall thanked the club for the support it had given him during the first year's existence of the club, which had enabled him to bring it up to a high standing.

In assuming the office, President Caverly said it would be his object during his incumbency to make the club a greater power than ever in the automobile affairs of Washington. Messrs. Wood, Mark and DeMoll were reelected, while Mr. Edmonds was promoted from lieutenant to captain. The latter has promised to devise a series of interesting tours for the club during the summer. An oyster roast was given by the club on New Year's day to members and invited guests.

OLDFIELD TO RACE IN CALIFORNIA.

Barney Oldfield has decided upon California as the scene of his exhibition track races, and he is on his way westward, this time under the management of Ernest Moross, who has again succeeded W. H. Pickens in a managerial capacity. Recently the latter issued a statement to the effect that he was no longer looking after Oldfield's tour. The energetic Pickens now has Eddy Bald and A. C. Webb for his champion-speed pair.

QUAKER CITY SHOW WINS OVER HANDICAPS

PHILADELPHIA, Jan. 9.—At 8 o'clock Saturday night last the annual show of the Philadelphia Automobile Trade Association, in the First Regiment Armory, was opened by Mayor Weaver, who touched the button that flooded the building with the light from a myriad of electric lamps, strung from the roof and scattered here and there through the foliage of trellised arbors which extend the length of the main hall. An unofficial

GENERAL VIEW OF THE MAIN FLOOR EXHIBITS.

opening of the exhibition had taken place in the afternoon, when possibly four thousand invited guests took advantage of the committee's invitation to inspect the exhibits before the evening rush.

The grossly inadequate show space afforded by the armory—the main hall is but 135 by 153 feet in dimensions—necessitated some Solomonesque adjudication to satisfy the claims of all the applicants for space, and that the committee seems to have satisfied nearly everybody argues well for their judicial acumen. All hands, however, seemed to realize the impossibility of getting a "quart foot into a pint shoe," and when the awards were made the members of the association were allowed to choose by lot the mid-floor spaces, the "unattached" tradesmen being relegated to the wall spaces and the quarters of the various companies on the first and second floors in the Broad street front. The result is that 51 exhibitors, including all the 37 concerns showing complete cars, are rather closely crowded together in the main hall, while the company rooms accommodate nearly a score of accessories exhibits—and everybody seems happy.

But this very dearth of space has turned out to be a blessing in disguise, for the committee was compelled to make arrangements for an auxiliary street show, including all the two score establishments which go to make up "Automobile Row," extending for three long blocks from Callowhill to Cherry streets. This feature was taken hold of with a will, and when the mayor turned on the current in the armory the same touch showed up both sides of Broad street for a distance of a third of a mile, decorated with continuous festoons of electric lights, which were reinforced by the individual displays of the agencies and branch houses, and managers of which seemed to vie with each other in making attractive displays in front of their several establishments. As a crowning feature the electric decorations of the City Hall, still in place from the annual New York celebration, were turned on and formed a magnificent background looking down Broad street. This feature will be continued throughout the week, and on Thursday night the general gayety will be added to when an automobile carnival, a huge fancy dress parade of autos of all varieties, will hold the boards. This has been divided into touring car, limousine and runabout divisions, and numerous prizes will

be distributed to the most tastefully decorated cars in each class. Although a few late applicants for space who desired to show cars and about a score of would-be sundries exhibitors were perforce left out in the cold, the committee feels that it has made no mistake in selecting the armory, if for no other reason than that demonstrations—a most important feature of local shows—can be given with convenience and dispatch. The close proximity of all the large "row" concerns and big garages permits of much more effective work in this particular than would have been possible had another and possibly larger but less conveniently located building been selected. The color scheme of the show is a combination of green, white and gold. The general effect is very pretty, although the overhead drapery is placed so low that it gives a squat appearance to the main hall.

As regards the number of different makes of cars on exhibition, the committee claims that the Palace show did not and that the Garden display will not equal it. About 55 distinct makes are represented in the 37 exhibits, of which seven—Mercedes, Fiat, Darracq, Rochet-Schneider, Hotchkiss, De Dietrich and Renault—are foreigners. Of the American cars the Matheson, Walter, Berliet, Pierce-Arrow and Packard seem to attract the most attention. At any rate, the combined exhibit is a most representative one, including about all the better known foreign and American cars.

Of the latter the only novelty seems to be the Autocycle, exhibited by the Vandegrift Automobile Company, of this city. It is a 6-horsepower runabout with single rear drive and single front steer wheels and with side bearing wheels. A maximum speed of 45 miles an hour is claimed for the Autocycle, and that it is a most easily handled vehicle can be attested to by the many who have been given a demonstration of its working qualities outside the armory.

The display of "battle-scarred" veterans is noteworthy. The winners in the recent endurance test, in all their hard-baked mud-diness, repose in the best places in the various booths, the Stevens-Duryea, the Autocar, and the Matheson (which, although disqualified, finished with a clean record), all contributing in this respect. At the De Dietrich booth is shown the very car which finished first in the Ardennes Circuit and third in the Vanderbilt Cup race, with the great Duray himself to add luster to the display. Joe Tracy and his racer are at the Locomobile stand.

Auxiliary Show of the Streets.

In addition to the "Overflow Show," which includes practically the third of a mile of "Row" establishments, there is an

AN ATTRACTIVE CORNER AT THE PHILADELPHIA SHOW.

auxiliary exhibition on the street outside the Armory, where the commercial vehicles and not a few pleasure cars lay all day, with conversation artists in charge, to descant on their merits. Here may be seen the Mitchell, National, Frayer-Miller, Deere, American, and other cars whose agents were unable to secure space, besides others for which there is no room in the rather limited allotment secured by their representatives inside, who were compelled to choose between which of two or more cars they prefer to show. The Kelsey Company, handling the Maxwell, is showing the new four-cylinder car at the salesrooms. The Quaker City Automobile Company, which handles six cars, gave up the attempt to make a comprehensive display, and but one each of the Pope-Hartford, Pope-Tribune, Pope-Waverley, Pope-Toledo, Franklin and Peerless is shown, the big salesrooms down the street housing the remainder of the exhibit.

as long as he could. At six o'clock Monday night it had scored nearly 130 hours. The car shows up at the Armory at intervals between trips to Wilmington, Norristown, Westchester, relays of operators and observers being taken on every few hours.

The Accessories Exhibition Is Quite Extensive

considering the limited amount of room at the committee's disposal. One of the features of the tire department is a demonstration of the process of making Ajax tires.

But two motorcycle exhibits were in place on Monday night—the Reading Standard and the Bradley—although the Simplex exhibit was expected to arrive at any hour.

Philadelphia Car for Vanderbilt Race.

A report going the rounds of the show has it that Philadelphia will be represented in the next Vanderbilt cup race, if not in

FIRST REGIMENT ARMORY, ON BROAD STREET, PHILADELPHIA, INSUFFICIENT IN SIZE TO ACCOMMODATE THE EXHIBITS.

W. J. Sprankle is in a similar fix, and is showing what he can of his Premier-Reo-Hotchkiss line. The Foss-Hughes Company, handling the Pierce, Cadillac and Baker electric; the Rittenhouse, with the Pungs-Finch and the Wayne; T. M. Twining, with the Crawford, Marion and Autocycle; the Spencer-Wilkie Company, with the Glide and Compound, and several other "Row" concerns are all working the double-exhibit scheme. There was no help for it.

The commercial contingent, for which there is absolutely no room in the Armory, is contenting itself with a street show outside. Among the cars in evidence are the Glidden tour Knox truck, the Reliance truck and the Mitchell delivery wagon, while the Autocar is showing a brand new delivery wagon at its salesrooms in the block below.

Martin & Hart, local Thomas agents, are making a big hit with the "60" Thomas which competed in the recent endurance run to Harrisburg. The car was started at the State Capital last Wednesday morning at 8.23, and the engine ran so beautifully all day that Aubrey H. Martin decided to keep it going

the final, at least in the elimination event. The car in question will be the Bergdall-Ambler, built by the recently organized Bergdall-Ambler Company, of this city, which is now erecting a huge salesroom, garage and factory at the northeast corner of Broad and Wood streets. Few details are obtainable, except that the car will develop 75 horsepower, and that the preparations have passed beyond the paper stage. The Bergdall-Ambler Company recently obtained the United States rights for the Benz, a German car.

The "first sale" competition, a feature of each recurring show here, was won by L. E. French, the local Cleveland agent, who disposed of a car to George S. Rominger, a local merchant, at 2.30 Saturday afternoon. The souvenir fiend even has a look-in. The local Glide agents are handing out a song entitled "A Jolly Old Ride in a Glide," and at the Quinby booth a handsome 12-page calendar exhibiting various styles of automobile bodies is being distributed gratis.

Among the numerous novel advertising schemes adopted by the various concerns, that of the White Company is attracting most

attention. Four huge kites hold aloft several American flags and a yellow banner setting forth the fact that the White is at the top of the heap. At night a searchlight, located on the roof of a nearby building, throws shafts of colored light on the kites and their burden.

Roll Call of the Philadelphia Trade.

The following are the active and associate members of the Philadelphia Automobile Trade Association:

Officers: President, Gilbert F. Smith; vice-president, H. Bartol Brazier; secretary and treasurer, George T. Thompson; assistant secretary, Arthur J. Pursell.

ACTIVE MEMBERS.

The Autocar Company, 249 North Broad street.
H. Bartol Brazier, 38th and Market streets.
Diamond Motor Car Company, 2119 N. Broad street.
Eastern Automobile Co., 326 N. Broad street.
Ford Motor Car Company, 451 N. Broad street.
Foss-Hughes Motor Car Company, 201 N. Broad strsst.
Gawthrop & Wister, 244 N. Broad strset.
Hamilton Auto Company, 206 N. Broad street.
Hills Motor Car Company, Broad and Chsrry streets.
Thomas B. Jeffery Co., 242 N. Broad street.
Kelsey Motor Co., 238 N. Broad street.
Keystone Motor Co., 238 N. Broad street.
Locomobile Company of Amsrica, 249 N. Broad street.
Marion Motor Car Company, 218 N. Broad street.
Martin & Hart Motor Car Co., 215 N. Broad street.
Mercedes Import Company, 153 N. Broad street.
Motor Shop, 317 N. Broad street.
Philadelphia Reo Motor Car Co., 242 N. Broad strset.
Quaker City Automobile Co., 138 N. Broad street.
Smith Mabley Co., 1407 Locust street.
Titman, Leeds Company, 316 N. Broad street.
Winton Motor Carriage Company, 246 N. Broad strset.
White Sewing Machine Company, 629 N. Broad street.

ASSOCIATE MEMBERS.

Diamond Rubber Co., 304 N. Broad street.
The Flak Rubber Co., 138 N. Broad street.
G & J Tire Company, 711 N. Broad street.
Jas. L. Gibney & Brother, 211 N. Broad street.
Hartford Rubber Works Co., 138 N. Tenth strset.
Michelin Tire Agency, 322 N. Broad street.
George W. Nock, 126 N. Fourth street.
Penn Auto Supply Co., 201 N. Broad street.
Pennsylvania Rubber Company, 615 N. Broad street.
Philadelphia Automobile Accessories Co., 2041 Arch street.
Paul P. Ripplen, 1207 Race street.
Ross Manufacturing Company, 910 Arch strset.

KANSAS CITY SHOW PLANS ARRANGED.

KANSAS CITY, MO., Jan. 7.—Kansas City's automobile show, March 4 to 10, will be in charge of an advisory committee appointed by the Dealers' Association, although a private organization will have charge of the details, subject to approval by the dealers. The dealers will get 50 per cent. of the net profits, pro rated according to the space they occupy. This ends a fight which has been waged for recognition by the dealers and in which they have been eminently successful. It has also resulted in the formation of an effective association, something the Kansas City trade has needed for a long time. Next year, according to the agreement made with the promoters of the show, the event will be entirely in charge, in all details, of the dealers. For this year space has been liberally taken in Convention Hall, of more than ample size to accommodate all exhibits. Interest in the show, in spite of its rather late date, is considerable and promises to give the trade a considerable boost.

After several preliminary meetings, the dealers got together January 3 and organized with the following officers: President, F. B. Doddridge, Missouri Valley Motor Co.; vice-president, C. F. Ettwein, Ettwein Motor Car Co.; secretary and treasurer, E. P. Moriarty, E. P. Moriarty & Co.; directors, W. R. Demster, Demster Machinery Co.; C. C. Meade, Ford Motor Co.; C. E. Cook, Palace Auto Co.; J. J. Wittman, Pope-Toledo Motor Car Co.; W. S. Hathaway, Buick Automobile Co.; Frank Bales, Cadillac agent.

CLEVELAND AND BUFFALO SHOWS CONFLICT.

CLEVELAND, Jan. 7.—The Cleveland and Buffalo local shows conflict in dates this year, coming exactly at the same time, but it is not believed that there will be any serious interference either in the matters of exhibits or attendance. Practically all the cars exhibited here will be shown through local agents, and the same is true of most of the lines of accessories, as the big Cleveland houses now handle practically everything that is built for or used on a car. The Cleveland show probably has somewhat the best of the bargain from the fact that it has secured a sanction from the motor and accessories manufacturers and will receive the support of that organization. It is claimed that had the local dealers been so inclined they could have nipped the plans of the Buffalo people before they were fairly developed. Instead they replied that they had no objection to the Buffalo show being held the same week, believing, as stated, that there would be no interference.

George Collister, manager of the Cleveland show, has received a communication from D. J. Post, president of the Motor and Accessories Manufacturers (Inc.), asking that the local officials do all in their power to correct one of the abuses which has heretofore annoyed people at local shows; that of allowing parties who purchase no space to roam from booth to booth with samples in their pockets and solicit orders.

WORCESTER TO HAVE AN AUTO SHOW.

WORCESTER, MASS., Jan. 7.—Frederick N. Prescott, promoter of the Portland and Providence automobile shows, plans to have a show in Mechanics Hall. It will be the first Worcester has ever had, and will be the first in New England this season, the Boston and other shows following a month or two later.

Mr. Prescott has room, according to his plans, for about twenty large exhibits, Worcester dealers being let in first. The only hitch will be in getting the big cars into the hall, which is of the two-story kind. If he cannot get the cars in the hall, he has arranged matters whereby he can secure other quarters in Worcester. There is scarcely any doubt about the show going through. Whether or not the Worcester Automobile Club will have anything to do with the affair has not been definitely determined, although President J. P. Coughlin is soon to be a dealer. As now arranged, the show will be held the week beginning February 11.

TEMPORARY RECEIVER FOR E. H. V. CO.

O'Brien, Boardman, Platt & Dunning, attorneys, of New York City, acting for four creditors of the Eisenhuth Horseless Vehicle Company, of Middletown, Conn., have filed a petition in the United States District Court asking that the company be declared bankrupt. Creditors named are Charles L. Hoffman and George D. Provost of New York, N. Townsend Thayer of Brooklyn, and W. F. Faulkner of Morris Park, N. Y., and the amount of their claims is \$1,107.91. They allege further that the company has more than twelve other creditors. Acting upon the petition, George T. Schull, of Middletown, has been appointed temporary receiver of the company, and is required to file a bond of \$50,000. The Eisenhuth company has had considerable financial trouble in the past, and the action taken was not unexpected.

TRADE CREDIT ASSOCIATION MEETING.

The annual meeting of the Automobile Trade Credit Association will be held Thursday evening, January 17, at the New York Athletic Club, at which time directors will be elected to fill vacancies. The meeting is scheduled for half past five o'clock in the afternoon, and will be followed in the evening by an elaborate dinner. The members of this association are located in all parts of the country, and are banded together for protection against the extension of credit to weak or unscrupulous buyers. Its aims are effected through mutual cooperation of the members throughout the country. The association's offices are located at 80 Wall street, New York City.

APPRAISING IMPORTED CARS FOR CUSTOMS DUTY

By HARRY W. PERRY.

UNUSUAL interest will center in the work of the United States appraisers at the port of New York during the present week because of the large number of foreign automobiles that will arrive on the European steamers for exhibition at Madison Square Garden.

Owing to the great urgency of giving the importing agents immediate delivery of the exhibition chassis and complete cars

REMOVING A CRATE FROM AN IMPORTED CAR.

as soon as they are landed, and to the limited facilities of the appraiser's office, a special arrangement has been made with regard to show cars. The appraiser has consented to permit the machines to be taken, as soon as landed, direct from the wharf to the Garden, where they will be examined and appraised for the collection of the import duty.

Probably very few automobilists except the regular importers, and possibly the rare American who purchases a machine abroad and brings it home with him, know anything about the routine that a car goes through in its passage through the Custom House when it comes into the country.

"In the first place," said Deputy Collector H. L. Swords, when interviewed in his office at Christopher and Washington streets, "the machine comes from the wharf on a truck to the government garage and the invoice is placed in the hands of the examiner. No examination is made until the invoice is in hand. The car is then stripped of its wrappings and examined as to horsepower, maker's number, and accessories. If the price entered on the invoice is found right the return is made to the Collector, and delivery is made of the car when the duty has been paid at the Custom House on Wall Street."

For more specific information as to the method of making an examination, the writer was referred to Examiner Thumb. "We verify the bore and stroke dimensions as given on the invoice by making measurements of the cylinders," he said. "We do not go by the horsepower ratings, which are given at the minimum on the other side because of the horsepower tax in France. Bodies and all regular equipment as commonly included when a car, as distinguished from a chassis, is bought, are assessed at the same rate as the chassis—45 per cent. duty. Separate bodies take 30 or 45 per cent. as manufactures of wood or aluminum, as the case may be.

"Cars are often passed in a day," said Mr. Thumb, replying to further inquiries. "Frequently cars that come into the garage in the morning are released the same day. The examination sometimes does not take more than ten minutes, if the invoice is all right. But sometimes the machine is away down in the bottom of the hold of the ship, and it takes two or three days to land it.

"We sometimes get as many as twenty-two machines in a day," he continued, "and if the importations continue to increase as fast as they have during the last year, it looks as if I would have to have some help."

Mr. Thumb is the only examiner of automobiles for New York, and the number of cars imported during the year just closed averaged close to five for every working day. Some interesting figures showing the rate of growth of imports were given by Assistant Appraiser Harvey T. Andrews, who exhibited a sheet of figures giving the number of automobiles passed through the Appraiser's office each month from May, 1903, to the end of 1906. As this was merely a private record kept for the convenience of the office, he declined to give it out for publication. But the statement showed that the total number of cars imported through New York for the year 1904 was 602. For the following year the number had increased to 1,054, and the year 1906 showed an increase of 50 per cent., the number reaching 1,561.

Some very interesting sidelights on the work of the Appraiser's office, and the enormous volume of goods that it is called upon to inspect, were given by Mr. Andrews. "This is the ninth division of the United States Appraiser's Warehouse," he said. "It passes all manufactures of wood, stone and metal, including automobiles. Last year the imports through this division reached a total aggregate value of \$95,000,000, of which \$5,488,690 represent foreign automobiles. You can get some idea of the marvelous increase in the country's imports when I tell you that the increase in this division alone is represented by import values aggregating \$25,000,000 more than similar imports during last year. This is only the increase, mind you, while eight years ago the total valuation of all imports passing through this division was only \$20,000,000. The importations of automobiles have been on a gradually increasing scale year by year. When the present tariff law was passed in 1897 there was no such thing as an automobile coming through the port, and so there is no specific provision in the law to cover them. But the increase has been so rapid of late that it became necessary last October to set aside a special building for their storage while awaiting and undergoing appraisal. This building affords 7,000 square feet of floor space, and will hold from twenty-five to thirty cars at a time, which number is sometimes exceeded when the imports are heavy, as they always are in October and in January. For instance, you see that October was the largest month last year, when 220 were brought in, and also in 1905, when there were 138. Probably more than 200 will come in during January this year, and next week there will be an unusual number because of the auto show.

PUTTING THE EXAMINER'S STAMP ON THE ENGINE.

It is of interest to note, by the way, that we are already beginning to feel the influence of balloons and airships. About this time last year we passed several for the automobile show, and a number came through since then, so that it looks as if we shall soon have airships as an article of commerce. At first the department was at a loss to know what division to assign them to, but finally gave them to our division because of our familiarity with automobiles and their engines, and because all manufactures of wood and metal pass through the ninth division.

"The renting of a separate building for automobiles minimizes the danger of scraping and marring the fine finish of the cars and also facilitates the handling. The building is at Christopher and West streets. When the machines are taken there they are under the control of the Collector, who acts as custodian. We have nothing to do with them until they are turned over to us with the invoices for examination, and when the examination is finished they are returned to his care. Our work is simply to put the price on them; the Collector's force calculates the amount of duty from the prices and rates we give, and then collects the duty for the Government."

UNLOADING IMPORTED CARS AT GOVERNMENT GARAGE.

In the background is shown the United States Appraiser's Warehouse, where hundreds of millions of dollars' worth of imports are handled annually.

Asked how the valuation of a car was arrived at, Mr. Andrews replied: "We keep posted on the prices of all makes of cars and chassis by means of price lists furnished from abroad, and frequently know the prices even before the importers. Then the prices must also be sworn to on the invoices. If the price is not on the invoice, or does not seem correct, we mark our own valuation on it, and nobody can force us to change that valuation. Either the importer or the Treasury Department can ask for a second appraisal, if the former thinks the price is too high or the Government thinks it is too low. Then, if one or the other is not satisfied with our figures, appeal can be taken to the Board of General Appraisers, on the seventh floor of this building."

As it may not be generally known how the high duty of 45 per cent. comes to be charged on automobiles when such machines are not specified in the tariff, the assistant appraiser gave the following explanation:

"The law provides that where *ad valorem* duties are assessed the value for customs purposes is that which obtains in the country from which the article is imported when sold in the usual and ordinary wholesale quantities. As there was no specific provision in the tariff law of 1897 covering automobiles, they are classified for duty under paragraph 183 of the tariff, otherwise known as the 'catch-all' paragraph, which provides a duty of 45 per cent. *ad valorem* on all manufactures of metals not otherwise provided for."

"How is it," Mr. Andrews was asked, "that the automobiles brought in for exhibition at the show all have to pay the full 45-per-cent. duty? Is there not a provision in the law or some

department ruling to the effect that cars can be brought in free if re-exported within a certain period, as three months or six months? The question has created some discussion."

"No," replied the assistant appraiser, "there is no such provision relating to cars for exhibition. When exhibits of any sort are brought in for world's fairs they are, by special arrangement, permitted to come in free of duty under bond, and if not sold the deposit under the bond is refunded when they leave the country inside of a certain period. In 1903 the Treasury Department made a ruling that a tourist might bring in a car under bond for three months' use in this country. Afterward this was limited to apply only to foreigners. This ruling was broadened again about a year later so as to include cars imported for racing purposes.

"So at present there are three cases in which a car may be imported free, the first being the case of a tourist from a foreign country, who, by giving a bond, can enter his car for three months; the second, that of a foreign firm which may import a car for racing purposes; and, third, the case of any person who has owned and used a car abroad for not less than twelve months, and who may import it free under what is known as the 'household effects' clause. Thus there is no provision in the law nor any department ruling that will let us admit machines for the annual shows free of duty. However, most of the cars put on exhibition are those of leading French, German and Italian firms, whose products have been so well advertised that the demand exceeds the capacity of the factories, and the cars seen at the shows are already sold or are certain to be bought before the shows end. In either case the car will remain in this country and duty will have to be paid, so that nothing would be gained by bringing it in free under bond, even if it could be done."

It will perhaps be of interest to add that any car taken abroad for touring and reimported, whether of domestic or foreign manufacture, is admitted free of duty, provided that only the ordinary necessary repairs and replacements have been made on it. This might include a set of new tires, a new lamp to replace one damaged, and other replacements, but if the car has been completely overhauled, repainted and refitted with foreign equipment, so as obviously to enhance its value, it must pay the regular 45-per-cent. duty, not merely on the increased valuation, but on the whole car and fittings. The only concession is that it will be appraised as a second-hand car, and the amount of duty to be paid will be correspondingly lower than on a new machine.

FROM THE INDIANA AUTO FIELD.

INDIANAPOLIS, IND., Jan. 7.—With factories already working overtime, all State agencies closed and sample cars displayed, and with several new concerns being organized and building plants, everything looks encouraging for a record-breaking output in Indiana this year.

Work has been started on the new plant of the Maxwell-Briscoe Motor Company at Newcastle, and it is expected that it will be ready for occupancy about July 1. Contracts for the foundation, calling for about 1,200 yards of concrete, have been let, and the steel work will be put up as quickly as possible. When completed, a force of about 1,200 men will be employed, and the yearly output will be fully 5,000 automobiles.

The Murillo Automobile Company, of Marion, has been reorganized as the Coppock Motor Car Company, and incorporation papers showing a capital stock of \$100,000 have been filed. Directors are: Harry Reynolds, M. Earl Brackett, Harry Ward and Lambert W. Coppock. It is the company's intention to manufacture a car suitable for carrying both merchandise and passengers.

Another new company is the Garrett Automobile Company, of Garrett. It has a capital stock of \$10,000, and will begin manufacturing automobiles shortly.

The Stanley Automobile Company, at Mooreland, is preparing to manufacture cars. One model, especially adapted for country and city use, will be made.

PLOUGHING THROUGH THE RICH RED MUD THAT ANSWERED FOR ROADS IN VIRGINIA AND NORTH CAROLINA.

OLDSMOBILE ON FLORIDA SOIL.

Despite the almost impassable nature of the country that has been traversed, the end of a week and a half of strenuous endeavor finds the variously christened Oldsmobile "alligator," "mudlark," and "pathfinder" across the Florida line, and almost within hailing distance of the long-sought goal.

Charlotte, N. C., was left behind last Friday afternoon, and after a strenuous drive of several hours the night was spent in a little place called Rock Hill—too small to be dignified by so much as a dot on the map. Whether Rock Hill is in North Carolina or South Carolina is a question that probably even the pathfinding party could not answer correctly. At all events, it is pretty near the line one way or the other, so that the next day's trip brought the party to Columbia—about half way across South Carolina, where the car and its occupants were greeted by the usual demonstration and bombarded with an endless string of questions regarding themselves, the car and the trip, not omitting a frequent invitation "to have something." The car and its passengers are arousing a great deal of curiosity.

Leaving Columbia the next day, Batesbury, S. C., was reached, where the next night was spent, another day's run bringing the party to Augusta, Ga., on the Savannah river, which marks the

boundary line between the two States. After crossing the river into Georgia the roads took on a totally different appearance and character. Instead of the red clay of South Carolina, which sticks to everything like a long-lost brother, the deep and shifting sand of the Georgia pine forests was encountered, and, so far as the running was concerned, there was not a great deal to choose between them. And the pines brought another disadvantage with them, for Sunday found the party lost in what appeared to be an interminable stretch of pine trees, so tall and thick as to practically shut out the sunlight. These woods are higher and the roads are excellent except that they are so narrow that there is scarcely room for the car to pass without the hubs striking the trees, and they wind in every direction of the compass so that they are utterly bewildering. It is like a beautiful mystic maze, but so puzzling as to render one absolutely helpless. After several hours of aimless wandering, a clearing was stumbled upon and, after inquiring the way of the inhabitant of the sole house in sight, it was decided to put up there for the night.

To go back over the route that has been followed, the party found themselves in Danville, Va., on the evening of New Year's day, but twenty miles having been covered since morning, when

A FORD IN VIRGINIA OF WHICH THERE WERE MANY.

A TOUGH CASE OF BLOCK, TACKLE, AND JACK.

IN EVERY SOUTHERN TOWN THE TOURISTS AND THEIR CAR WERE A SOURCE OF MUCH WONDER AND EXCITEMENT.

Chatham, Va., was left. The roads are sticky red clay, which is a close brother to the "gumbo" mud of the West. This surfacing is a foot or more in depth and makes hard pulling under any circumstances, but on long upgrades the strain is terrific as such a mass of it has to be carried and shoved along by the car. But worse than the mud are the mud holes; they were always filled with water and gave no hint of their depth, so that the car frequently plunged into mud and water three or four feet deep, the differential being hung up on a rock every now and again so that the rear wheels would spin around with the engine racing at full speed until shut off. It was a good deal like a ship in a heavy sea with its propeller coming out of the water unexpectedly. Going like this has made the block and tackle, shovels and four pieces of plank the most valuable things on the car, and if there is any distinction to be made, it must be awarded to the planks, for they have proved to be worth their weight in gold.

Three miles an hour has frequently proved to be all that could be averaged, and the hour usually entailed forty-five minutes' strenuous labor with sapper's tools for every fifteen

minutes of driving. The roads surpass description; they are the worst imaginable, sometimes being totally submerged for long stretches so that the car swishes along with the mud and water almost up to the running board. The natives state that the roads in question are not used at all during the winter except in cases of urgent necessity, and then extra horses are required to make any progress at all. Mr. Owen thinks they are far better at certain seasons of the year, and with proper attention would soon be available all the year round. North Carolina has carried off the palm in this respect. The roads near the Virginia line in that State have been far and away the worst that have been encountered on the trip, and, though not a great deal better, there was sufficient difference in the southern part of the same State to make a distinction between them. Of course, a hotel is practically an unknown quantity in any place but the towns, though the people throughout the South are very hospitable.

Everywhere that a stop has been made the natives have been obliging and ready to lend every aid in their power, though frequently this has not been much, even in the line of information, and information in that section is essential.

A TYPICAL VIRGINIA HOME.

THERE ARE REAL BRIDGES.

CHAINS IN MUCH DEMAND.

A TRYING PENNSYLVANIA ENDURANCE RUN

PHILADELPHIA, Jan. 7.—The first annual endurance run of the Quaker City Motor Club, from this city to Harrisburg and return, last week was a most successful affair, thirteen of the original twenty-four starters finishing within the time limit. The winner of the Stillman Class B cup for cars costing \$1,500 or less turned up in W. George Brooks' Autocar, which had but five points penalty chalked up against it.

F. THOMPSON'S STEVENS-DURYEA WHICH FINISHED FIRST.

The fight for the honors in Class A developed a double protest against the only perfect-score cars—the Matheson and the Stevens-Duryea. The former was ruled out at Harrisburg by the committee for equipment shortcomings, its special testing body not conforming to the rule regarding touring-car trim. Mongini, who was at the wheel, took his disqualification with equanimity, left the capital at the specified time and finished without the shadow of a demerit. The protest against the Stevens-Duryea was an eleventh-hour surprise, and was filed by T. W. Berger, entrant of the Oldsmobile, which finished second in Class A, it being claimed that the Stevens lost its muffler on the outward trip, and continued the run minus that necessary article of automobile furniture, which would constitute a violation of Rule 8 of the conditions governing the contest. Berger, by the way, had very hard luck. His Oldsmobile had arrived at Harrisburg on the first day twenty-one minutes ahead of time, and was waiting behind the line, with motor running, for the officials to check him into the control, when some of the mud picked up on the way worked into the carbureter and stopped the engine. The mishap cost him the only two points charged against his car. This unusual cause of stoppage demonstrates more clearly than any word description the extraordinary bad conditions of the road. Even on a very muddy road with a moderate under-surface foreign matter will never penetrate to the carbureter. Only axle-deep mud could reach this important organ.

The protest filed against the Stevens-Duryea was subsequently allowed, but the penalty inflicted, one point, did not change the relative standing of the cars, as the Oldsmobile, which finished in second place, had two points charged against it. The local Matheson people have their car on exhibition at the Armory show, labeled "The only car which finished the endurance run with a perfect score."

A protest filed against Charles Hoffman's Simplex, on the ground that it was not fitted with a regular touring car body, was also sustained, and the car returned to Philadelphia as a free lance, doing "first aid" work and acting the Good Samaritan generally.

Some Things That Happened to the Participants.

"Wally" Owen had hard luck with his Cleveland. After plowing through the mud on the first day, and passing all the inter-

mediate controls on his schedule time, he was within half a mile of the Keystone Garage in Harrisburg—the official stopping place—when the engine stopped owing to overheating, due to a leak in the radiator. When he checked in "Wally" was 49 points to the bad.

One particularly plucky performance was that of No. 4, Aubrey H. Martin's 40-horsepower Thomas Junior. Four miles beyond second control on the outward trip—Sadsburysville, 45 miles—the main shaft snapped in half. After a council of war the crew decided to repair it. There was no machine shop at Sadsburysville, and, leaving Observer J. R. Baltz to watch the car, the others trudged back through the deep mud four miles to Coatesville, where they finally located a small shop—closed on account of the holiday. They hunted up the owner, and he accommodatingly gave them the run of the establishment. In ten hours they managed to finish up a substitute, and then floundered back through the mud and darkness to where the crippled car lay—with the faithful Baltz curled up fast asleep in the tonneau. With only the light afforded by the car's lamps, the new shaft was put in, and at 3:25 the next morning, having lost fourteen hours, the trip was resumed. Harrisburg was reached at 8:04 A.M., and the return trip was started at 8:13. The makeshift shaft made good, and the finish was made on schedule, although the car had been ruled out for not finishing the first leg of the course within the limit.

Highway Conditions a Striking Object Lesson.

The road conditions, especially during the first day's run, were simply frightful. A three-days' downpour had made quagmires of all but the best roads. Thirty of the thirty-seven miles between Lancaster and Harrisburg were so bad that the finishing of twenty-two of the twenty-four starters is considered little short of remarkable. If there was ever an object lesson given for the necessity of immediate road improvement in Pennsylvania the first midwinter run of the Quaker City Motor Club amply demonstrated it. There is no reasonable argument, barring the existence of a heavy fall of snow, to be advanced against a winter trip, such as was projected and carried out by the club, and the very fact that it was successfully accomplished speaks wonders for the pluck and endurance of the participants and the cars that were driven over the well-nigh impassable highways, if in reality, some of them are worthy of being dignified by that name.

The movement for highway improvement in the Keystone State will necessarily be advanced by the recent run, as it will bring the citizens of the commonwealth to a realization of the

W. G. BROOKS AND HIS WINNING AUTOCAR.

conditions existing, such as no other practical demonstration would be capable of presenting. The route, with the official controls, distances and schedule time, was as follows:

FIRST DAY, JAN. 1.	Distance.	Time.
Philadelphia to Malvern.....	23.1 miles	1 h. 30 min.
Malvern to Sadsburyville.....	21.5 "	1 h. 5 min.
Sadsburyville to Lancaster.....	22.7 "	1 h. 20 min.
Lancaster to Elizabethtown.....	19.4 "	1 h.
Elizabethtown to Harrisburg.....	17.4 "	1 h. 20 min.

104.1 "

SECOND DAY, JAN. 2.

Harrisburg to Lebanon.....	25.2 miles	1 h. 40 min.
Lebanon to Reading.....	29.3 "	1 h. 25 min.
Reading to Pottstown.....	20.6 "	1 h.
Pottstown to Norristown.....	15.5 "	1 h.
Norristown to Philadelphia.....	18.9 "	1 h. 30 min.

109.5 "

2. Oldsmobile; owner and driver, T. W. Berger.....	2
3. Lozier; owner, M. E. Brigham; driver, H. Michener.....	3
4. Studebaker; owner, E. C. Leeds; driver, F. H. Yerger.....	17
5. Oldsmobile; owner, G. H. Gantert; driver, John Tallies.....	48
6. Locomobile; owner, Richard Sellers; driver, J. W. Flonda....	53
7. Cleveland; owner and driver, Wallace Owen.....	117
8. Thomas Flyer; owner and driver, E. R. Kelly.....	191
9. Cadillac; owner and driver, F. W. Stockbridge.....	211
10. Stearns; owner, L. D. Berger; driver, O. H. Hoffman.....	324

H. B. Stillman Cup, Class B.

1. Autocar; owner and driver, W. G. Brooks.....	5
2. Rambler; owner, G. W. Barbier; driver, Harry Wallis.....	230

The Frayer-Miller car, which won the Berkshire Hills economy run of the New York Motor Club last November, finished No. 11 in Class A, a series of disheartening tire troubles giving it 709 points in penalties.

DELAWARE'S GOVERNOR HAS SUGGESTIONS.

WILMINGTON, DEL., Jan. 7.—The Delaware Legislature, now in session, will probably make some changes in the automobile law passed at the last session. The biennial message of Governor Preston Lea contained the following:

"The protection of the public against careless and reckless motorists has rendered necessary a revision of the present law touching motor vehicles. Accidents arising from automobile driving are frequent. Excessive speed is the chief cause and inspires the dread and prejudice on the part of the traveling public against automobiles. As a vehicle of utility the automobile should be recognized as possessing the same right as all other vehicles in the use of our highways, subject, however, to certain restrictions inherent in the character of these machines. I recommend that the present law be so amended as to provide:

"1. For an annual payment of a license fee of \$5 by the owner of every motor vehicle.

"2. For the annual payment of a license fee of \$2 by chauffeurs.

"3. For the revocation of all licenses under proper restriction, upon proof that the licensee is an incompetent or reckless driver.

"4. For the employment by every person incompetent to run a motor vehicle of a licensed chauffeur.

"5. For the payment of all such license fees, together with all fines and forfeitures imposed under the provisions of the law; to the State treasurer, who shall carry such funds to a highway improvement fund to be expended pursuant to a proper highway improvement statute.

"Pecuniary penalties have not proved effective in checking reckless and careless driving. Fine and imprisonment has been demonstrated to be the only effective check, fine for the first offense and fine and imprisonment for all subsequent offenses."

With Russian caviare concealed in the hollow rims of his automobile, a smuggler was recently detected by customs officials crossing the Russo-Austrian frontier near Cracow.

T. W. BERGER'S OLDSMOBILE, WHICH FINISHED SECOND IN THE QUAKER CITY MOTOR CLUB'S ENDURANCE RUN.

THE COLUMBIA GASOLINE-ELECTRIC.

Electricity has long been regarded as promising a solution of the vexatious problem presented by the "gearless" car which represents the aim of the designer. While others have been seeking this end along the path of multiplication of cylinders in order to attain the infinitely flexible motor, the Electric Vehicle Company has been studying the problem from a totally different point of view, that of interposing an electrical connection between the motor and the driving wheels instead of a mechanical union such as is at present typified by the usual clutch and change speed gears in which pinions are slid into mesh. The latter is a system that has always been reputed to violate the first principles of engineering, and the frequency with which early change speed gears were wrecked seemed to bear this out.

Nor has the motor of many cylinders solved the problem, although in the hands of a skillful driver it has been found possible to cover long stretches of country that would call for frequent changes of gear with the ordinary four-cylinder motor in the hands of the ordinary driver. Multiplication of the number of cylinders has undoubtedly marked a step toward the realization of the gearless, but whether it will in the end prove to be a step that will result in the achievement of this goal, or merely one taken in the wrong direction, remains to be seen. In the meantime, the long step that has been taken toward the development of electricity for the same purpose is of considerable interest. The idea of utilizing the power of the motor to generate an electric current which was reconverted into mechanical power through the medium of electric motors has been one that has appealed to investigators in this field for the past several years, and numerous systems have been devised, the majority of them involving the use of a storage battery, while the location of the motors has varied in others, being placed directly at the wheels in some cases, and directly behind the generator in others, a mechanical connection being employed in driving on the high gear in the latter case.

This is the form that has been adopted by the Electric Vehicle Company after close to two years' experimenting with various modifications of the system, during which period the new chassis has been put to continuous and severe tests under service conditions to bring out any latent defects such use would tend to reveal. As will be seen from the accompanying plan view of the new gasoline-electric chassis, the flywheel of the ordinary motor has been displaced by the generator which is direct connected to the crankshaft of the motor and which hardly occupies more space than the wheel which it displaces. In other respects the motor is of the standard four-cylinder vertical type employed on the Columbia cars. Immediately behind the generator the motor is placed, though, as already mentioned, there is no mechanical connection between the two on any but the high speed when the crankshaft of the motor and the propeller shaft terminating at the live rear axle become solidly coupled and both the dynamo and motor run dead.

The lower speeds, of which there are five forward and a reverse, are all provided by means of a small lever similar to the controller handle employed on street railway cars. This actuates the electrical controller connected to the generator and the motor and permits of the variation of the voltage and amount of current sent into the latter in order to obtain the range of speeds mentioned. This is effected by throwing the windings of the generator armature and field into different electrical relation with the armature and fields of the motor in order to avoid the use of a dead resistance which would merely waste the current at low speeds. No storage batteries are employed, thus greatly simplifying the power plant and the wiring as well as greatly reducing the weight, which has always been the disadvantage of cars on which it was a feature. The low speeds are used in starting, the motor being capable of a heavy overload, and when up to speed a clutch is employed to couple the motor and propeller shafts and the car runs exactly the same as one equipped with the usual change speed gear.

CHASSIS OF COLUMBIA GASOLINE-ELECTRIC CAR.

FRENCH GRAND PRIX AND THE GOVERNMENT

PARIS, Jan. 1.—Owing to persistent assertions in usually well-informed quarters that the French Government intended to withhold permission for the Grand Prix, the Automobile Club of France departed from its usual plan and sent a deputation to wait upon M. Clemenceau, President of the Council. In previous years a circuit has been first selected, and only when the various local and district authorities have given their approval to the scheme has the club asked for Government permission. Headed by the Baron de Zuylen, president of the A. C. F., the commission, consisting of Baron de Turckheim, Louis Renault, M. Darracq, M. Brasier, René de Knyff, M. Collot, and the Marquis de Dion, waited upon M. Clemenceau on December 26 and urged the necessity of an annual speed contest, as in the past. One of the arguments put forth was that if the race was abolished exportations would decrease. "Americans," declared the Baron de Zuylen, "only buy cars which have made a name for themselves, or, at any rate, only buy from those countries victorious in international contests."

The head of the Government having objected that the old regulations appeared to have rendered all the services that could be expected of them, and to no longer contribute towards the amelioration of touring or town cars, M. René de Knyff explained that with the new regulations limiting the fuel supply to 30 liters per 100 kilometers, it was hoped to obtain marked improvement in automobiles. Economy in fuel consumption, improvements in transmission, and reduction in the weight of chassis will, said M. Brasier, result from the new regulations.

M. Clemenceau was of opinion that the fuel consumption was high, and, before giving a definite and official reply, asked the club to prepare a report, giving the old and new regulations, and submit it for the examination of Government experts. He assured them that there would be no delay, and, immediately received, the report would be studied and a prompt reply given. By January 15, at the latest, the Government decision will be known. The committee will urge: (1) The commercial advantages which French constructors have obtained from races; (2) the progress made in automobile construction for a number of

years owing to speed contests; (3) the attention which foreigners pay to the French Grand Prix, and the hope they have that this event may be forbidden in France. The A. C. F. is confident that M. Clemenceau, who has always shown himself liberally disposed towards automobilism, will grant the necessary permission.

Several circuits have been proposed, the latest favorite being one at Soissons, near Compiègne, one hour from Paris. The 1907 circuit must have good, wide roads with a very hard soil, must not be less than 38, or more than 60 miles round, have no control, neutralizations or grade crossings, must be near some important center with railway and lodging facilities, and must be as near Paris as possible.

Proposed Auto Legislation in the French Chamber.

When the 1907 budget proposal came before the French parliament a few days ago a strong effort was made by certain deputies to put a heavier financial responsibility on automobilists and the motor industry. An increased annual taxation on every automobile was first proposed, but rapidly abandoned. Would-be chauffeurs then received attention, a proposal being made to impose a tax of two dollars on every person applying for a license to drive an automobile. A stiff struggle took place between the motor and non-motor section before this was abandoned. There is a probability of the tax being brought up again on the next occasion. Finally two deputies of the Loire district, basing themselves on what takes place in Germany, proposed a graduated tax on all foreign machines entering France for touring. For four-cylinder cars the proposed scale was \$2 per day, \$12 per month, \$25 for four months, and \$50 for a stay of not more than one year. A formidable array of figures was brought forth to prove the importance of the train of gold left behind by foreign visitors, and after discussion the *Chambre des Députés* decided, for the present, not to submit American millionaires to further imposition when traveling over the good roads of La Belle France. It is estimated that over 3,000 foreign cars toured in France last year.

A GOOD ENTRY FOR THE EMPEROR'S CUP

PARIS, Jan. 1.—With an entry list of 39 cars, likely to be increased by another dozen by the end of the year, the success of the race for the German Emperor's Cup on the Taunus circuit, June 14, is already assured. Fiat heads the engagement list, with Lancia, Nazzaro and Weillschott as her champions. Then follow Opel, Benz, Metallurgique, Bianchi, Mercedes, Adler, Protos, Minerva, Fahrzeug Fabrik, and English Daimler, most of them with three machines. On the closing of American mail France is represented by three Darracqs, to be driven by Wagner, Hanriot and Demogeot, one Mors and three Lorraine-Dietrich to be piloted by Duray, Rougier and Gabriel. Further French engagements are expected before final closing. Brasier participation will depend on the decision of the company directors to-day. N. Levavasseur, designer of the Antoinette motors, famous in motor boats and aeroplanes, gives hope of participating in the German race. Renault and Panhard, on the other hand, will certainly not compete.

Nominally a touring competition, the German Emperor's Cup is in reality a speed contest for machines with a cylinder capacity limited to 8 liters, and weighing not less than 1,175 kilos with racing body and tires, but without gasoline, oil, water or spare tires. The circuit will have a length of about 52 miles, to be covered six times, giving a total of rather more than 300 miles.

Although the exact course has not yet been decided upon, it is certain that a portion of the 1904 Gordon Bennett circuit will be utilized. Three projects are before the German Club, and a final decision will be made early in January.

The course having the most chances of being accepted starts from Hamburg to Saalburg, Wehrheim, Usingen, Graevenwiesbach, Noettau, Einhaus, this portion being the 1904 Gordon Bennett course. At Einhaus, instead of turning to left, the road continues straight to Weilburg, and at the entrance to this village turns sharply to the left and returns by Essershausen, Ernsthausen, Schmitten and Ober to Hamburg. This circuit gives forty-eight miles to the round, which, being cover five times, makes a total distance of 240 miles. There are no controls or neutralizations. Unless state affairs intervene, the German Emperor will be present at the race bearing his name.

Final entries for the German race closed at Paris and Berlin on December 31, the entrance fee being 3,000 marks per car. Gasoline and tire stations on the course are rented at an additional 1,000 marks. It has been found necessary to close the entry list six months before the date of the race in order to leave time to choose a circuit suited to the number of cars engaged. Tires and gasoline men are allowed until May for engaging stations.

WHAT MASSACHUSETTS' GOVERNOR RECOMMENDS

BOSTON, Jan. 7.—In his inaugural address to the Legislature, Gov. Curtis Guild, Jr., made some very radical recommendations for new automobile legislation, and some which are not at all relished by the automobilist. His recommendations included one for a new tax based on horsepower, and one for an examination board before which every applicant for a chauffeur's license must appear. His recommendations in part were as follows:

"Another source of taxation that I believe to be equitable is this: that he who is especially responsible for the waste and damage of public property would pay for any unusual damage that he causes. The suction of the automobile tire, for instance, is the cause of exceptional damage to the roads of the Commonwealth. I recommend a tax on all motor cars proportionate to horsepower, the entire proceeds to be devoted to the maintenance of State highways. I firmly believe that such a tax would alike remove much of the present complaint against this mode of locomotion and would vastly add to the comfort of all who use the highways for any purpose.

"It is evident that in another direction the Highway Commission must be given ampler powers. The abuse of automobiles is not decreasing; it is increasing. No engineer can take charge of a steam boiler without an examination. A locomotive engineer must serve a long apprenticeship before he is put at the throttle, though he moves only over set rails, on a line where every vehicle but one like his own is a trespasser. The automobile chauffeur, without any examination, sometimes an overconfident young man, sometimes an inexperienced girl, is turned loose on the public highways in control of an engine nearly if not quite as dangerous as a locomotive. Not even a law as to right of way checks collisions with other vehicles.

"I recommend that, as the sailing vessel has the right of way over the steamer on the high seas, so the horse and pedestrian shall for like cause be given, as the weaker, the right of way over the automobile on crossroad and highway.

"I further recommend the establishment of a board of expert examiners for chauffeurs, acting under the Highway Commission. I recommend that no person, owner or chauffeur, without a certificate of examination in reasonable practical tests in motor management, shall be longer permitted to experiment with dangerous engines on the roads of Massachusetts, at the risk of the lives of the citizens of this Commonwealth."

What the Massachusetts Autoists Think About It.

Though many of the automobilists are inclined to wait a little before giving their opinion, there is a general feeling among them that something in line with the governor's recommendation for a board of examiners would be a good move. The examination should not be too drastic and searching, but it is admitted that it is too easy at present to secure a chauffeur's license. Even a strict examination, however, would not prevent reckless and careless driving, as some of the most expert chauffeurs are sometimes reckless and are often the fastest drivers. It is thought that the proposed examination should be more strict for professional chauffeurs than for owners.

In the matter of right of way the automobilists are also inclined to agree with the governor, although they would like to have a law, if it were passed, so administered as to make horse drivers and pedestrians obey the laws of the road as well as automobilists. It is feared that if a law were passed some horse drivers would interpret it to mean that they could monopolize the whole road to the exclusion of the automobiles.

In the matter of the horsepower tax, it is hard to find an automobilist who will agree with the governor. The automobilists point out that horsepower is an extremely variable quantity; that it has no direct relation to speed or weight, both of which factors are of the most importance in the effect of an

automobile on the highway. It is suggested that if the State needs more revenue, and it is found constitutional to impose another tax on automobiles, an annual registration fee, the same for all machines, and an annual licensing fee for operators would produce the necessary revenue.

The Highway Commission in its annual report will ask for an appropriation of \$50,000 additional for repairs on the highways for damage caused by automobiles, and it is to secure this additional money that the increased tax is proposed. In its annual report the commission will devote much space to a consideration of the effect of automobiles on the State road, but it will state that it believes that it is in a position to cope with the new conditions of traffic provided it has a sufficient appropriation. The commission will make only minor recommendations regarding the automobile laws, leaving the drastic recommendations to the governor and the special committee on taxation, which is preparing a report on possible sources of increased State revenue.

During the fiscal year ending November 30, 1906, the Highway Commission will report that the gross income from automobile registration and licensing of operators has been \$33,087.50, an increase of more than \$8,500 over the twelve months of 1905. The net income for 1906 was \$19,587.50, an increase of almost \$10,000 over the net income of 1905. During the eleven months of the new fiscal year of 1906 the commission registered 6,572 automobiles, 666 motorcycles and issued 151 manufacturers' or dealers' certificates. It issued in the same time 4,649 ordinary operators' licenses, 3,391 new professional chauffeurs' licenses, and 2,043 renewed professional chauffeurs' licenses.

The growth of automobile registration and the licensing of operators since 1903, when the first automobile law was passed, is shown in the following table:

CERTIFICATES OF REGISTRATION.

	1903.	1904.	1905.	1906.
Automobile	3,743	4,261	4,889	6,572
Motorcycles	533	666
Manufacturers and Dealers....	100	80	102	151
LICENSES TO OPERATE.				
Ordinary Operators	3,907	3,585	3,736	4,649
Professional Operators	692	1,335	2,392	3,391
" " (renewed)	741	2,043

During the first two years the registration of motorcycles was not kept separately from that of automobiles. In 1903 the gross income from the business was \$17,684. In 1904 it increased to \$19,162, and in 1905 to \$24,490.50. On account of the change in the fiscal year of the State, the figures for 1906 cover only eleven months, but the gross income in that time was \$33,087.50. In the same time the expenses increased from \$5,531 to \$13,500.

NEW YORK'S GOVERNOR ON GOOD ROADS.

ALBANY, N. Y., Jan. 7.—In his first message to the New York State Legislature, Governor Hughes commented upon the importance of the good roads movement in the following manner:

"The constitutional amendment of 1905 authorized an indebtedness not exceeding \$50,000,000 for the improvement of highways. For the first time the State has undertaken the construction and maintenance of roads in a systematic manner. It has been reported to me that surveys and plans for the improvement of about 2,500 miles of main roads have been approved by the various boards of supervisors throughout the State; that of these 2,500 miles about 800 miles have been constructed, and that in addition between 500 and 600 miles are under contract and will be completed during the coming year.

"With the exception of three counties, every county outside of Greater New York has petitioned for improved roads. It is of great importance that this work should go forward and that the system of main highways should be completed with expedition."

FRELINGHUYSEN ALMOST A STANDPATTER.

NEWARK, N. J., Jan 7.—Senator Frelinghuysen, author of the automobile law that has been beneficial or detrimental to New Jersey, according to the viewpoint, is inclined to make few changes in the present law. Interviewed by a *Call* reporter, the senator is quoted as follows:

"With reference to automobile legislation, you may say for me that I believe the bill passed last winter has been beneficial in its effects. While it was somewhat in the nature of experimental legislation, yet I believe it has demonstrated its usefulness, the main defect being, in my opinion, inadequate provision for the proper enforcement of the law."

The senator continued: "The bill, as originally presented, called for a force of twenty-one inspectors, one for each county in the State. Experience has demonstrated that this force is inadequate, and I am in favor of amending the bill by making an additional force of twenty-five inspectors, appointed to serve without pay. That this plan is feasible is demonstrated by the fact that some of the best inspectors under the old law were appointed from the ranks of the automobilists and served without pay. Already applications have been received from this class of autoists who desire proper observance of rights of highway."

Senator Frelinghuysen concluded the interview by remarking: "At present I do not see the necessity for any radical change. I am very much opposed to any change in the speed limit."

It is also understood that Commissioner Smith, of Trenton, who is chief of the department, has some notions regarding automobile legislation that he hopes to be able to have Senator Frelinghuysen draft in any amendments that may be made.

PROTECTIVE ASSOCIATION IN BALTIMORE.

BALTIMORE, Dec. 31.—At a well-attended meeting of the Automobile Club of Maryland, the Automobilists' Protective Association of Maryland was organized for the sole purpose of securing the amelioration of conditions that the automobilists claim are intolerably oppressive, in regard to the speed law. In the new organization there are neither membership fees nor dues, and all the members were pledged to use their influence for the election of officials who will give automobilists a square deal. The following officers were elected: President, Osborne I. Yellott; secretary, Charles B. Finley. An executive committee will be appointed by President Yellott in the near future. Whenever needed the league is to actively enter upon political campaigns to attain their ends, and will do everything in their power to right what they consider an injustice. The following resolution was unanimously adopted:

We, the motorists of Maryland, as a body, stand unequivocally in favor of the adoption and strict enforcement of such laws as are reasonably necessary to protect the public at large from the reckless and unreasonable use of the automobile on the public highways of the State, and to punish those who, by their handling of automobiles in any way endanger the safety of such public; but are unalterably opposed to any law or mode of enforcing the law which results in the punishment of an entire class of persons for the wrongful acts of a few of that class.

MINNESOTA TO HAVE SOME LEGISLATION.

MINNEAPOLIS, MINN., Jan. 7.—A new automobile law is being prepared for submission to the Minnesota legislature. The law is to be the joint product of the automobile clubs of Minneapolis and St. Paul, and will provide for a new system of registration for cars throughout the State. The law will also provide that large cars cannot be driven by persons under twenty years of age. A penalty will also be provided for proper punishment of chauffeurs who use cars without permission, and for the apprehension of those who pick up machines on the street.

The legislative committee of the Montreal Trades and Labor Council will request the Dominion Government to pass a law prohibiting the employment of youths below a certain age in driving delivery wagons or acting as chauffeurs of automobiles.

COMMENDS AUTOS FOR POSTAL USE.

WASHINGTON, D. C., Jan. 7.—A very interesting document is the annual report of Frank H. Hitchcock, First Assistant Postmaster General, and it is doubly interesting to the automobile world for the mention made of the use of automobiles in the postal service. That portion of the report is as follows:

"During the past year, for the first time in the history of the department, arrangements were made for the introduction of an automobile service in the collection of city mail. Under a contract that went into effect on the 1st of October last, two specially equipped automobiles are being utilized in the collection service of Baltimore. Favorable reports have been received regarding them, and the department is now planning for a similar collection service in several other places. It is believed that in large cities automobiles can be advantageously substituted to a considerable extent for the horse carts now employed so generally in collecting mail. By the use of automobile vehicles a much speedier collection service can be organized without added expense. Plans are now being considered also for the introduction of the automobile in other branches of the city postal system with the purpose of quickening, as far as possible, the handling of the mails. Unquestionably the motor vehicle can be made an important factor in the postal service, as it already is in other business enterprises."

VERMONT WANTS REGISTRATION RECIPROcity.

MONTPELIER, VT., Jan. 7.—The principal features of the new automobile law, recently passed here by the Vermont legislature, are a speed limit of 10 miles per hour in cities, villages and thickly settled territory, and 25 miles per hour outside. The penalty for violation of this provision is \$50 fine or ten days in jail, or both, for the first offense, and not over \$200 nor less than \$25 fine, or six months in jail for subsequent offenses.

The registration fee of \$3 is for machines of 20 horsepower or less, and \$5 for machines of over 20 horsepower, with an operator's license of \$2. The fee for a distinguishing mark of a manufacturer or dealer is \$25. Residents of other States or countries are not obliged to take out a license in this State if Vermonters are allowed a like privilege in the State from which the visitors come.

A penalty is provided for operating machines while in a state of intoxication, and the rear sign on the machine is to be illuminated at night or during a heavy fog by light from the outside. The new law is silent in regard to closing any of the State highways against automobiles, and has no impounding clause. It goes into effect on February 1.

40-H.P. LOZIER WITH NEW YORK SELLING FORCE.

In the car going from the Broadway salesrooms to the Madison Square Garden Show are C. A. Emise, S. Regar, W. S. Mead, F. C. Chandler, O. F. Thomas, Rene Beauchenien, and H. Michener, demonstrator.

THINGS DOING AMONG THE GARAGES.

Model Garage to Be Built at Little Rock, Ark.

A contract is about to be let by the Little Rock Auto Company for the erection of a handsome new automobile garage on the lot recently purchased by them at 311 West Third street. The building will be of pressed brick, two stories high, occupying a floor space of 52 by 118 feet, fireproof, and constructed according to the latest design for up-to-date garages. Inside arrangements will include offices for the members, ladies' separate waiting rooms and private lockers for customers. A compressed air machine for inflating tires will be installed with a line of hose running the entire length of the building, affording an easy means of inflating the tires to any machines as they may need it. There will be a fireproof oil house for lubricating oils and an underground tank for gasoline. An elevator and turntable will also be installed. E. P. Ladd is president, John F. Boyle, vice-president, and M. A. Treadway, secretary and treasurer, of the Little Rock Auto Company, with about thirty other Little Rock citizens as shareholders.

Pittsburg Will Have Two New Garages.

The Winton Motor Carriage Company's Pittsburg branch will begin at once the erection of a new garage to replace the one destroyed by fire a few weeks ago. The new building will have a frontage of 120 feet on Beatty street and will be three times the size of the old structure.

Manager McGiehan, of the Rainier agency, will open a downtown garage this month and will provide a good stopping place for owners of cars who drive into town in the morning or for out-of-town people who come into Pittsburg when touring and want a central place to stop.

Auto Inn Garage at Elyria, O., Increases Its Space.

N. R. Spear is now a part owner of the Auto Inn automobile garage, at Elyria, O., having purchased the interest of H. B. Hine line in that concern, and takes over the active management. The whole of the lower floor of the building has been secured and during the winter months facilities for the convenience of the trade will be installed.

BRIEF NOTES OF THE GARAGES.

Doud Brothers, of Chatsworth, Ill., automobile dealers, are preparing to build a new garage. They will carry agencies for the Buick and other cars.

It is reported that a garage 60 x 140 feet is to be built in Erie, Pa., at the corner of Sixteenth and State streets, or a building erected partly for garage use and partly for other purposes.

Kansas City, Mo., now boasts its first large electric sign as the result of the progressiveness of an automobile dealer. This is over Kingsley's garage and spells the latter word out in prominent letters.

Schwender Bros., Mankato, Minn., will shortly occupy the lower story of the garage building just completed for Fowler & Pay. It is of brick construction and is modern throughout in fitting and appointments.

Two recent additions to Philadelphia's garage facilities are the DeLancey garage, at Twenty-second and Pine streets and the Fifty-third street garage, at 420 North Fifty-third street, the latter under the management of F. R. Bayle.

A new building for the L. H. Fawkes Auto Company is to be erected in St. Paul, Minn., early in 1907. The plans have been drawn, and provide for a roomy garage, with a partial second story. The new place will be conveniently located on Sixth street.

Ballston Spa, N. Y., is to have another garage. It will be located at the corner of Front street and Milton avenue and will be in the shape of a two-story building of brick, erected by George West for Tracy W. Nichols. Cars will be handled on the first floor and the offices and machine shop will be on the second story.

A remodeled building of the three stories, on Sixth street, St. Paul, Minn., is to be occupied as a garage and salesroom by the C. P. Joy Automobile Company, which has operated on Minnesota street for two years. The Joy brothers control a big portion of the St. Paul trade, handling the Pierce, Packard, Franklin, Pope-Hartford and Waverley lines.

In order to accommodate its rapidly expanding business, the Acme Garage, Tacoma, Wash., has begun work on an addition measuring 50 by 100 feet, to be erected in the rear of its present establishment, giving a total floor space of 200 by 140 feet. In addition to representing two or three different makes of cars, the agency for a number of patented sundries has been obtained.

Jacksonville, Fla., is to have an up-to-date garage. L. C. Oliver, the local agent of the Ford Motor Company, of Detroit, Mich., recently bought out the Duval garage at 29-33 West Forsyth street, and will remodel the building in order to accommodate a much larger business. J. E. McCants, who conducted the Duval garage for the past four years, will be manager of the repair department.

The Citizen's Motor Car Company has just successfully concluded negotiations for the purchase of the northeast corner of Main and Seventh streets, Cincinnati, at a cost of \$110,000, and will immediately begin the erection of a three-story concrete garage, to occupy the entire plot, which measures 93 by 130 feet, at a cost of \$100,000. The company was recently incorporated with \$100,000 capital, which will shortly be increased to \$250,000. J. W. Tarbille, formerly with the Williams Valve Company, will be the general manager of the concern.

C. J. Bronson, who represents the Winton and Cadillac interests in Grand Rapids, Mich., has recently more than doubled the floor space of his garage at 42 to 50 Kent street by the addition of an annex 75 by 100 feet. This makes a building 100 by 125 feet on the ground floor and 50 by 100 feet on the second floor, the first floor being entirely clear, as it is unencumbered with posts. The Bronson garage is the largest Michigan's capital city can boast of, the next in size being that of the Richmond-Jarvis Company, at 11-13 Park street, with 12,000 square feet of floor space.

FAKE NUMBER TAGS AND CHAUFFEUR BADGES.

ALBANY, Jan. 8.—When Police Commissioner Bingham sent a representative to-day to ask Secretary of State Whalen for permission to copy the complete list of registered automobiles and chauffeurs in the State on file in his office, it became known that there is in New York a factory which turns out false badges for chauffeurs and false number tags for automobiles.

Executive Clerk James L. Mock, who was Commissioner Bingham's representative here to-day, told Mr. Whalen that the New York factory had turned out at least 10,000 badges for chauffeurs and numbers for automobiles. Only a few days ago, Mr. Mock said, the police arrested a chauffeur whose badge bore the number 26,000, while the highest chauffeur number on file at the office of the Secretary of State is 16,195.

There are about 40,000 automobiles and more than 10,000 chauffeurs registered here.

HOW THE LITTLE SPRING MOTOR RUNABOUT LOOKS.

AN AUTO FOR YOUNGSTERS.

The Elite Junior is a small automobile intended for the use of children, and its weight does not exceed sixty pounds. This miniature car is equipped with artillery wheels and ball bearings, pneumatic tires, oil lamps, horn, number tag, and an imitation coil box. Instead of a gasoline engine or electric motor, it depends upon a large steel coil spring for its source of energy. The speed of the car is never greater than five miles an hour, while the power is being used, and it is extremely simple to operate, there being only two foot pedals that need attention. The spring motor is wound up by a crank handle, and is so geared that it becomes very easy for a child to wind. The car is designed upon the lines of an up-to-date runabout.

MICHELIN HAS NEW AMERICAN AGENT.

E. Lamberjack, of Paris, who for a long period has been the export agent for the entire product of Michelin et Cie. of France, is at the present time in New York City, and has formed a company and taken over all the rights, effects, and good will of the Michelin Products Selling Company, Inc., of 31-33 West Thirty-first street, New York City. The new concern will be known as E. Lamberjack & Co., Incorporated, and will occupy the offices and salesrooms heretofore occupied by the Michelin Products Selling Company.

Under the new arrangement Michelin et Cie. will deal directly with their patrons in America, through the new house. One of the innovations will be a material reduction in the price of Michelin tires, which has been brought about through this arrangement.

NEW CORRESPONDENCE SCHOOL FOR OWNERS.

Makers generally have long realized that one of the chief causes at the foundation of most of the minor troubles encountered by the average autoist, is to be found in the ignorance of the latter. In other words, the automobile is one of the few pieces of machinery that is permitted to fall into the hands of men with practically no technical knowledge or experience. Various makers have appreciated the need of a better knowledge of the mechanism of their own cars on the part of those who purchase them or are to drive them, and have provided instruction of one kind or another, but efforts in this direction have not been attended with flattering success in every instance.

The Maxwell-Briscoe Motor Co. is about to enter this field in a totally novel manner. It has added a department to be known as "The Correspondence School of Motor Car Practise" for the benefit of owners of Maxwell cars principally, though others may benefit by it as well. The course consists of a series of lectures, supplemented by the text-book "The Making of an Automobilst," and other pamphlets on special subjects.

The school will be conducted by H. A. Grant, and will include among its other features a "Question Department." The cost of the complete course where owners of Maxwell cars are concerned, has been merely made to cover the cost of printing, while for others it is slightly higher.

ALCOHOL TOO HIGH FOR PRESENT MOTORS.

As was predicted by the knowing ones last spring, when the legislation relieving alcohol from taxation which went into effect on the first of the year was being promulgated and its optimistic supporters were prophesying the relegation of gasoline to the background, Joe Tracy's recent 100-mile run, using the new fuel, proved that while its use is perfectly feasible in the present-day motor, it is far from economical. Speaking of his experience with it, Tracy said that "aside from the price of the fuel, I found that a very much larger quantity of it was needed than of gasoline. We used about three times as much alcohol as we would have required of gasoline to do the same work. We did not get quite as much power. This, of course, was due to the fact that the compression was not high enough. Had we been using an engine built to use alcohol we could have done much better."

In addition to the explanation afforded by the above statement, it must be taken into consideration that the test was carried out under the most adverse conditions and that, aside from recording the total quantity of fuel consumed, no data of any kind was taken. There is little doubt that with a specially designed engine using high compression and long stroke and the lower price of the fuel that is bound to come when it has been on the market longer, a far more favorable showing would result. As it is, the chief fact of importance established by the test is that alcohol may be used in the standard motor without any changes whatever, and this alone is of considerable interest.

POPE COMPANY TOO BUSY FOR RACING.

TOLEDO, O., Jan. 7.—The announcement of the Pope Motor Car Company, through H. S. Leyman, assistant manager, that it will not participate in racing events this season, will come as a distinct surprise to those who have followed automobile racing since its inception. The Pope Motor Car Company has always been an aggressive competitor in every event in which it has entered, and has always been one with which to reckon, as the many trophies which adorn the company's office will testify. No reason is assigned for the decision to eliminate racing this season, but it is probably due to the heavy demand for standard cars, which is taking every possible effort the company can make.

A. G. SOUTHWORTH, NEW YORK POPE REPRESENTATIVE.
IN HIS POPE-TOLEDO.

NEWS AND TRADE MISCELLANY.

New machinery is being added by the Swinehart Clincher Tire and Rubber Company, of Akron, Ohio, which will allow an increase of 50 per cent. over present output.

E. P. Moriarty & Co., of Kansas City, Mo., are looking for a licensed car of popular price to add to their line. They are in the market for something to sell at less than \$2,500.

Starting at exactly 12:01 on the morning of January 1, Manager Thomas Hay of the Chicago branch of the Ford Motor Company claims the first 100 miles run of the year in the new 1907 six-cylinder Ford touring machine.

Plans have just been begun for a new building to be added to the Mason Motor Car Company's plant at East Fifth and Vine streets, Des Moines, Ia. The addition will be two stories high, 44x100 feet, and will be metal sheeting.

The records of the license clerk in the office of the city clerk at Cleveland show that 956 automobile licenses were issued by the city last year, indicating that between \$2,000,000 and \$3,000,000 was spent for automobiles in the Forest City last year.

An increase from \$200,000 to \$1,000,000 has been made in the capital stock of the Glidden Varnish Company, of Cleveland, O., to meet increasing business and provide for further extensions. The company's new factory is rapidly approaching completion.

The Hayes Manufacturing Company, of Detroit, Mich., states that it is incorrect that their plant, or any part of it, has been removed to Lansing. A branch has, however, been opened at Lansing in the Olds gas engine plant to take care of the firm's increased volume of business.

Behen-Faught Motor Car Equipment Company now occupies the entire first floor at 3961 Olive street, St. Louis, next to the Diamond Rubber Company agency. Dust-proof fixtures are specialized. Jno. J. Behen, George Maynard Faught, Ed. S. Studer, S. F. Behen comprise the executive staff.

Mrs. J. H. Cuneo, of Richmond Hill, N. Y., has just placed an order with the Rainier Company for a 35-horsepower Rainier car, which will be delivered to her in March. Mrs. Cuneo has achieved distinction in numerous race meetings and was the only female driver to compete in the 1906 Glidden Tour.

A site has been purchased and the erection of a new factory building commenced at 9 Center street, Detroit, for the Ross & Young Machine Company, doing business at 133-135 Farmer street in automobile parts and general machine jobbing. The firm expects to begin business in their new plant about March 1.

Owing to increased volume of business the Piqua Blower Company, of Piqua, Ohio, is being incorporated under the laws of that State with a capital of \$50,000. This corporation will take over the interests of the Piqua Foundry and Machine Company and will make a specialty of positive blowers and gas exhausters.

In response to recent advertisements, orders for 25 car loads (100 runabouts) were received in one day, December 24, by the Ford Motor Company. Immediate delivery of Ford machines is guaranteed by the firm's system of running the factory at its full capacity every week in the year.

The December output of the factory was 42 cars per day; on January 2 it was increased to 50 per day.

Colonel Edward S. Fowler, appraiser of the port of New York, states that during the year 1906 1,561 automobiles, including 128 domestic cars, of the total appraised value of \$5,488,690.11 were imported at this port, the corresponding figures for 1905 being 1,054, including 80 domestic cars, valued at \$3,972,297.31, and for 1904, 603 cars, valued at \$2,209,492.11.

W. Hildreth, manager of the Holsman Automobile Company, of Chicago, states that on January 21 the price of their Model No. 9 machine will be advanced to \$700 and their Model No. 10 to \$750. The firm's new factory, first occupied eight months ago, is now working to its full capacity, and more space will soon be planned. In 1907 the output will be from 1,500 to 2,000 machines.

Last week G. W. Gammack ran a regularly equipped stock model electric Columbia victoria-phaeton 75 7-8 miles on one charge of the battery, averaging a speed of fifteen miles an hour. This is the highest mileage recorded in any of the company's tests, and speaks conclusively for the superiority of this model. Mr. Gammack was handicapped over most of the distance by a driving rain.

The Hartford Rubber Works Company, of Hartford, Conn., has received the following letter from Clarkson Limited, motor car and omnibus manufacturers of Chelmsford, England: "We think you will be gratified to learn that one of the 34"x3½" tires originally supplied to us by you has now done about 27,000 miles upon a 16-passenger omnibus, and is still running. T. Clarkson, Managing Director for Clarkson Limited."

In the past year the Autocar Company of Ardmore, Pa., has installed 46 pieces of new machinery in their machine shops. One of the largest and most important pieces is a Landis crankshaft grinder which alone cost \$1,800. The nicety of the construction of this machine may be better understood when it is known that the Autocar system of factory tests requires each crankshaft bearing to be ground to the fineness of a fractional part of one thousandth part of an inch.

The Allyn Brass Foundry Company, of Cleveland, has now three plants running in full operation at Cleveland, Buffalo and Detroit, making it one of the largest producers of brass and aluminum castings in the world. Work has been commenced on additional buildings on the Detroit plant. Pierce Smith, formerly of the J. D. Smith Foundry and Supply Company, of Cleveland, is now connected with the Allyn Brass Foundry Company, and is representing them on the road.

The Minneapolis tire show became a one-day affair, January 5, instead of three days, as planned. The refusal of the tire manufacturers to allow northwestern representatives to exhibit resulted in the confining of the show to local repair houses and manufacturers and retailers of accessories. The big room of the clubhouse was well filled during the afternoon and evening. Exhibits were made by L. H. Fawkes & Company, the J. N. Johnson Company, O. Renstermacher & Company, the Evans Motor Car Company, and W. P. Shattuck.

The new four-story branch house of the Winton company, on Sherman square, Broadway and Seventieth street, New

York, is one of the finest automobile establishments in the world. The building contains 84,000 square feet of floor space, and, having been constructed exclusively for automobile purposes, has every conceivable up-to-date facility. The manager of this establishment, C. W. Churchill, was formerly a Cleveland. His elevation to the New York management illustrates the Winton idea of giving preference in appointments to men in the Winton ranks.

The entire 1907 output of the Autocar Company, of Ardmore, Pa., has been sold to the following dealers: Geyler & Levy, Chicago; Middleton Motor Car Company, San Francisco; Fred S. Smith, Boston; Williamsburgh Auto & Storage Company, Brooklyn, N. Y.; Motor Car Company, of New Jersey, Newark; Thomas & Lowe Machinery Company, Providence; J. H. Brady Auto Company, Detroit, Mich.; Palace Auto Station Company, Hartford, Conn.; R. V. Conneerat, Savannah, Ga.; Citizens Motor Car Company, Cincinnati, Indiana Automobile Company, Indianapolis; Mr. Vernon Car Company, Baltimore; O. L. Barringer Company, Charlotte, N.C.; Colburn Auto Company, Denver, Col.; U. S. Automobile Company, Rochester, N. Y.; Wilmington Auto Company, Wilmington, Del.; Harry R. Hoppes, Westchester, Pa.; Norris Auto Company, Saginaw, Mich.; Youngs & Company, Newburgh, N. Y.; Autocar Sales Company, New York City; Standard Auto Company, Cleveland; Broadway Auto Company, Seattle; August Stocker, Salt Lake City; Cook Auto Company, Portland, Ore. One hundred cars have been reserved for the Philadelphia branch. The factory is now running night and day in order to make prompt deliveries.

NEW AGENCIES ESTABLISHED.

The Auto-Motor Car Company, 804 Sycamore street, Cincinnati, has taken the agency for the Rainier for southern Ohio and eastern Kentucky.

The Newark Rubber Tire Company, of Newark, N. J., has opened a repair department at 266 Halsey street, under the management of John F. Moran.

D. P. Nichols & Company, the newly appointed agents for the Frayer-Miller in Boston, have opened a salesroom in the Motor Mart, Park Square, that city.

The Franco-American Auto and Supply Company, 1404-1406 Michigan avenue, Chicago, has been appointed selling agent and distributor for the Michelin tire for the central and middle west.

The Bonney Motor Car Company, of Kansas City, Mo., has taken the garage at 1112 Locust street, formerly occupied by the Western Automobile Company. The company is Kansas City agent for the Wayne.

The Keystone 'Auto Company, of Pittsburg, Pa., has decided to open a downtown salesroom in the new Fulton building on Sixth street, where it will display its line, consisting of the White, Welch, Ford, and Stoddard-Dayton.

A permanent office has been established in Chicago, by the Willard Storage Battery Company, of Cleveland, to take care of its western automobile battery trade. The office is located in room 1535, First National Bank building.

E. L. DeCamp, of Kansas City, Mo., has taken the sales agency for the entire output of the Mason car, built in Des Moines, Ia. The car is of the double opposed two-cylinder type and has shown up well on the hills of Kansas City.

The Big Four Automobile Company, of Los Angeles, Cal., recently organized by C. S. Anthony, T. Morehouse, and Walter Heist, has secured the agencies for the Marmon and Monarch cars, and opened a salesroom at 110-14 East Ninth street.

Frank Bales has taken the agency for the Cadillac in Kansas City, Mo., and for the present will find quarters near Fourteenth on Walnut street. Later in the season he will erect a roomy garage at Admiral boulevard and Grand avenue, opposite the Midland hotel.

Chas. F. Kellum & Co., manufacturers of the well known Invader oils, have opened a retail branch at 648 North Broad street, Philadelphia, and another one at 715 Seventh avenue, New York City. The home office and warehouse of the company will remain at 128 Arch street, Philadelphia.

Agencies for the Jackson line have been placed by Ralph Temple, the Chicago representative, with C. H. Farnum, Baraboo, Wis.; Manly Brothers, Harvard, Ill.; and Jacob Dreishire, for Sandwich, Somonauk, and Plano, Ill. Thompson & Lipscomb, will represent the Jackson at Lacon, Ill.

The W. & N. Valve Lifter, described in the December 6 issue, is now controlled by the Auto Specialty Company, Chicago, A. J. Jackson, manager. This concern is also the general selling agent for the Standard Lamp Company, and has the Western agency for Gilt Edge polish and other specialties, and is adding new lines rapidly.

Lyons & Company, Grand Forks, North Dakota, have been appointed agents for the Franklin and Cadillac for the northern part of that State. This house handled the Franklin last year, and have recently taken on the Cadillac, also the agency for Indian motorcycles. They do an extensive supply business, covering all the territory west of Grand Forks to Montana.

That individuals and tradesmen may receive prompt attention and deliveries, the Hartford Suspension Company is establishing agencies in various parts of the country. Among those recently established were The Springfield Automobile Company, Springfield, Mass.; the Dominion Automobile Company, Ltd., of Toronto, Winnipeg, and Montreal, for Canada, and the Chanslor & Lyon Motor Supply Company, of Los Angeles and San Francisco, for California.

A new departure by the National Battery Company, of Buffalo, is the establishment of the National Battery Depot, at 271 Michigan avenue, Chicago, with George S. Berger in charge. A complete stock of electric vehicle and sparking batteries and parts will be carried, so that prompt renewals and repairs can be made of any standard sized battery as well as the National. The company's Chicago sales offices will remain, as heretofore, at 450 Old Colony building, in charge of Bertram Smith.

RECENT TRADE REMOVALS.

On January 1 the Chicago branch of the Rainier Company removed to its new salesrooms and garage, located at 1725-7 Michigan avenue.

The Jones Speedometer has moved its Boston office to 109 Massachusetts avenue, near Boylston street. Manager A. L. Lucas will remain in charge.

The Coppock Motor Car Company, recently organized, has purchased the Murillo Motor Car Company and is incorporated at \$100,000. Light and heavy motor trucks for delivery wagons will be constructed, and it is the intention of the company to build pleasure vehicles later. Officers of the

Company are M. Earle Brackett, president; W. M. Myers, vice-president; H. F. Reynolds, secretary; Harry Ward, treasurer; H. W. Coppock, general superintendent.

All manufacturing of Ajax tires will hereafter be done at the Trenton, N. J., plant, the New York factory having been moved to Trenton, where the Ajax-Grieb Rubber Company's assembled plants now are. General offices have been opened at Fifty-ninth street and Broadway, New York City, pending the completion of the company's new offices which will be ready about February 1. The offices of the president and the sales department are now located at Fifty-seventh street.

PERSONAL TRADE MENTION.

At a meeting of the board of directors, held January 2, Nicholas Guy Roosevelt was elected treasurer of the Dragon Automobile Company, of Philadelphia.

Owing to press of other business, O. E. Seager has retired as vice-president of the Jackson Auto Company, of Kansas City, Mo., although retaining his stock. His place will shortly be filled.

Joseph F. Gunther, manager of the Chicago branch of Thomas B. Jeffery & Company, is enjoying a three weeks vacation in Mexico. He will journey as far south as the capital city before he returns.

Raymond Martinez Hernandez has been appointed western agent for the Continental Caoutchouc Company, and will have charge of all the territory west of Chicago, with the exception of California.

H. F. Siegrist, formerly treasurer of the Swinehart Clincher and Rubber Company, of Akron, O., has severed his connection with that concern, and is succeeded by Frederick Boron for the unexpired term.

J. A. Swinehart, of the Swinehart Clincher Tire and Rubber Company, of Akron, O., who has been in Europe since the middle of December, is expected to return about January 15. He reports a giant stride in the Swinehart tire outlook abroad.

The latest accession to the ranks of the Dragon Company is Al Poole who is best remembered as the mechanic who rode with Joseph Tracy in all his Vanderbilt races. Poole is an expert mechanic and tester and will prove a useful addition to the Dragon forces. He recently rode with Joe Tracy on the alcohol test of the Dragon car held on New Year's Day, and is now working with the latter on engine tests.

Recent changes in the personnel of the managers of the branches of the Diamond Rubber Company, include the appointment of C. H. Smith as manager of the Chicago branch at 1523-31 Michigan avenue, and W. P. Cronin as manager of the New England branch at 174 Columbus avenue, Boston. Both Messrs. Smith and Cronin have had extended service with the Diamond company as salesmen in the territories over which they are to preside, and are thoroughly familiar with local conditions and requirements.

NEW TRADE PUBLICATIONS.

From the Outcall Manufacturing Company comes a colored tear-off calendar illustrating a familiar roadside scene in summer.

"Trophies Won" is the frontispiece of the Jackson Automobile Company's catalogue describing the firm's different models for 1907.

By text and design the brochure issued by P. M. Hotchkiss, 4021 Lake avenue, Chi-

cago, shows the vibrations of a car with and without the Hotchkiss anti-jolt device.

"Just a Moment," a scene at a railroad crossing, is the catcher with which S. F. Bowser & Co. holds up the motorist for a second to instruct him in the proper methods of handling and storing gasoline.

The Corcoran Lamp Company's tear-off calendar will certainly be retained and hung up in every office in which it is received. "The Signal," the central embossed and colored design, is a highly artistic piece of work.

Tinkering is not recommended, but the Pope Motor Car Company believes that any intelligent man can take care of Pope-Waverley electrics with a little instruction, and has issued a booklet of instructions to meet this end.

Light is cast on the subject of automobile and portable reading lamps by the Avery Portable Lighting Company's booklet just received. It shows how the Auto-gas tanks will light up the road before you or prove of use in country homes.

Elegance has been sought and attained in the Detroit Steel Products Company's hanging calendar for 1907. On a plain brown ground a maiden fair and wondrous beautiful presents the products of a fruitful autumn. Embossed and artistically colored, the calendar will rank among one of the best of the season.

A very comprehensive and practical automobile handbook, in the German language, has been published by M. Krayn, 11 Kurfurstenstrasse, Berlin, under the title "Automobiltechnischer Kalender und Handbuch der Automobil-Industrie fur 1907." The book was compiled from all available reliable sources by E. Rumpier, a well-known Berlin engineer, and explains and illustrates the construction of gasoline, steam and electric automobiles and their component parts, and also takes up in detail the subject of motor boats. Instructions are given for caring for automobiles of various types and practical hints given on their care and maintenance. The book includes a calendar, with blank spaces for notes, and a series of useful mathematical tables for handy reference; also rules for making various calculations required in automobile and motor work.

A SIMPLE FORM OF CAR.

The Auto Buggy presented by the Success Auto Buggy Manufacturing Company, of 530-540 De Baliviere avenue, St. Louis, Mo., is an automobile in its most simplified form. Briefly, it consists of a buggy carried on a V-shaped steel angle-iron frame with 37-41 or 40-44 wheels, either rubber or steel shod. The motor is a two-cylinder air-cooled type, 4 inches bore by 4 inches stroke, with fan in fly-wheel and positively balanced to avoid vibration, and is carried on the side of the buggy, transmitting power to rear wheels through a side chain without the intervention of a differential. Planetary transmission is employed with connecting rods and levers which are operated by pedals on the inside of vehicle. There is a 14 inch stationary steering wheel guaranteed not to rattle. Dickinson ball-bearings are employed for the road wheels, and are guaranteed absolutely water-tight. The importance of this cannot be overestimated for a machine employed on rough work over wet and sandy roads. The chief feature of the buggy, however, is the direct transmission, without differential. The invention of John Clark Higdon.

INFORMATION FOR AUTO USERS.

Quick-Acting Wrench.—There is a vast amount of time lost in adjusting monkey-wrenches, and there are plenty of men who have done this by the roadside on a cold day who have wished for something less tedious than the apparently endless screw arrangement. To meet this demand the York Electric and Ma-

YEMCO QUICK-ACTING WRENCH.

chine Company, of York, Pa., has brought out the Yemco quick-acting adjustable wrench. In general appearance the Yemco wrench is much like the well-known adjustable wrench; but in the sliding jaw is a little button. Press this button and the jaw can be slid to any desired point, and on releasing the button will be held there securely. One advantage of this wrench is that it can be manipulated with one hand. It has another important feature. The jaw can be placed in any position, and its position can be changed by the most minute degrees—there are no fixed points of engagement. The worm which takes the place of the usual thumb worm turns easily and automatically as the jaw is moved up or down.

Quad Ignition Timer.—The ingenious timer illustrated herewith is the product of the Quad Manufacturing Company, of Columbus, O., and embodies a number of features that make for durability and accuracy. The illustration is so clear that the construction is easily understood. The shaft has two bearings, front and back, so that there is no tendency to bind and wear unequally. The peculiar form of the shaft, cut away at one side, permits the use of a very large roller, of hardened steel, running on a hardened steel pin. This insures long life to the

very large indeed for the work they have to do. The dome-shaped cover is of polished aluminum and carries the front bearing; the back piece is of gray iron, and in it is formed the main bearing. Insulation is of fiber and the contact blocks of steel; the shaft, carrying the steel roller, is of bronze. The arm carrying the roller is on a pivot and the rounded face of the roller is pressed against the contacts by a spiral spring attached to the opposite end of the arm. A felt oil retainer keeps the oil where it belongs and excludes dust. To remove the cover it is not necessary to take out the two retaining screws; they are merely loosened and the cover slightly rotated, when it can be removed, the screw heads passing through holes cut for the purpose.

"Ever Ready" Autometer.—There is a marked tendency among automobilists to clear the dashboard as much as possible. Thus the Ever Ready, combining minute and second clock, speed indicator, and sea-

FACE VIEW EVERY READY AUTOMETER.

son and trip record is likely to meet with favor among up-to-date automobilists. The instrument has a 4 inch dial, figures are large, distinct and proportional and can be read at a glance from the back seat or from any other part of the car. The mechanism and governor, working on the principle of centrifugal force, are theoretically and practically correct. There are no soldered joints or loose pieces and the apparatus is inclosed in a solid bronze dust and water-proof shell. The 65 miles universal indicator above described, complete with flexible shaft, gears, etc., is listed at \$75 by the Auto Improvement Company, 316 Hudson street, New York. Another instrument handled by the same company, without the clock, registers up to 9,999 miles for the season, and 999-10 miles for the trip, and is sold at \$70 complete. All Ever Ready speed indicators are mounted on patent adjustable brackets, allowing the instrument to be turned to right, left, face up or down, as may be desired by the operator.

An Effective Non-skid.—The Midgley Wire Grip is not a new tire, as some have seemed to think, but an effective non-skid arrangement, originated by The Hartford Rubber Works Company, consisting of five endless coils of spiral wire embedded in the flat tread a short distance from and parallel with each other. In practice each

MIDGLEY WIRE GRIP TIRE.

of these coils presents a minute wearing surface flush with the outer rubber in the tread. Now the more the tire wears down the better the non-skid device works, because each one of the coils is practically an inverted staple, taking direct and positive hold of the road or street surface over which it passes.

This is an absolute preventive of side-slipping under any and all conditions. Furthermore, the wire coils are so arranged that they have a slight co-operative action with the rubber, and thus subtract nothing from the resiliency of the ordinary pneumatic. While this construction prevents skidding, it adds to the "life" and wear of the tire. A Hartford Dunlop, or Clincher, fitted with the Midgley Wire Grip, is sold at an average advance of 25 per cent. over the plain casings.

The Hartford Rubber Works Company now offer to American owners of high-grade foreign cars Clincher tires made in millimeter sizes, exactly fitting the rims on all types of foreign cars.

For the first time non-skid devices are available in millimeter sizes incorporated into the tread itself. At the present time they are prepared to supply 12 different sizes but their factory is equipped to turn out any others for which sufficient demand is had.

The dimensions of these tires are not approximate, but exact. They will fit perfectly the rim on foreign cars, requiring no costly or time-consuming delays when that equipment is decided upon.

A Novel Guideboard.—It is pretty hard lines to find a guideboard so faded out that the lettering is almost invisible, especially if one is in an automobile and the weather is bad and the light failing. It's a case of getting out in the mud or snow and going up to the board to puzzle out the dim directions. A new kind of guideboard has been invented by W. P. Harmony, of 627 Franklin avenue, Sidney, O., to avoid this trouble, and it is called the Fadeless Guideboard. The

CROSS SECTION QUAD IGNITION TIMER.

wearing parts, as the roller rotates at comparatively low speed. Moreover, there are special means for constant lubrication, a dustproof oil hole opening into a little reservoir from which oil flows through suitable ducts to the bearings. While the Quad timer is of very compact build, the roller is of maximum size and the shaft and its bearings are

letters are formed by series of cup-shaped indentations in the wood, painted a color contrasting with the paint on the rest of the board; the hollows hold the paint and protect it from the effects of the weather. Even without any paint at all the inventor states that these signs are perfectly legible, and that nothing short of the destruction of the board will deface the inscriptions. The wood used is cypress, and boards are sent out with lag screws for attaching to posts. They cost no more than the ordinary type. Protecting ledges are placed at the ends and top.

Stewart Speedometer.—As a proof of the care which is bestowed on the construction of the Stewart Speedometer, a five years' guarantee is given by the manu-

FRONT VIEW OF THE STEWART.

facturers, the Stewart & Clark Mfg. Co., 69-71 Wells street, Chicago. Having no fragile mechanism, no delicate hair springs, brass sliding parts, or soldering, the speedometer can be relied on to indicate accurately speed and distance traveled over all kinds of roads. A feature of the Stewart apparatus is a flexible shaft made of steel links that hook one into the other without riveting or splicing and which is guaranteed not to crystallize or break. While practically indestructible, in case of accident it can be easily repaired in a moment's time. Extra hooks are supplied and it requires no tools to make the repair. The shafts are mounted on ball bearings of extra quality and finish. Pivots and other bearings are mounted in hardened steps, and both steps and pivots are highly polished to reduce friction. All swinging members are mounted on long hardened pivots with step bearings. The Stewart universal joint allows the flexible shaft to hang at any angle; it obviates short bends and prevents the shaft from crystallizing and breaking.

Double Swivel Vise.—It is often necessary, when the automobilist is so unlucky as to be forced to make roadside repairs, to do all kinds of stunts to hold a bit of metal steady enough to file; and it is a very difficult matter to file off more than a very small amount of metal while holding the work by hand. Some kind of a vise would be just the right thing, and the Pittsburg Automatic Vise and Tool Company, of Pittsburg, Pa., has brought out a vise exactly suited to these conditions. To the running-board or step of the car is attached a small and unobtrusive base, which is a fixture; and

the vise is attached to this, when it is to be used, and at other times is safely packed away in the toolbox. There is no complication about the insertion of the vise into the base—it is simply set in the socket, in which it is perfectly free to turn in a complete circle. As soon as the jaws are tightened on a piece of work, however, the vise is automatically clamped in its base and cannot move. Release the work and the vise is again free to swivel. There is another swiveling motion. The jaws can be swung clear around on the axis of the screw, and, as in the case of the horizontal movement, the tightening of the jaws on the work clamps the swivel automatically. These movements make it possible to get the work into almost any imaginable position for convenience of access in filing and so on. The vise has 13-4-inch jaws, opening 31-2 inches, weighs 31-2 pounds and is nickel-plated. The parts subjected to stresses are of alloy steel and the screw is a steel forging; all parts are interchangeable. The company also makes shop vises of all sizes on the same principles.

New Vulcanizer.—Engine troubles in these days are rare, but tire difficulties still remain with us. With the Ever Ready Vulcanizer, controlled by the Auto Improvement Company, 316 Hudson street, New York City, the automobilist is able to quickly and easily make any and all kinds of repairs to inner tubes, repair all cuts, sand blisters, and sections of tread, without removing the shoe from wheel. The distinguishing feature of the Ever Ready system of vulcanizing consists in the use of a special rubber compound, which is used

EVER READY VULCANIZER.

to fill in all punctures, blow-outs, cuts, or sections of tread, which have been removed or become detached from the canvas, and in all cases dispense with the use of patches and with the reuse of any of the old rubber, which has been removed, hence the damaged portion is in every case provided with absolutely new rubber.

The apparatus is made of tempered aluminum, is very portable, weighs only 31-2 pounds and is provided with a full set of tools, materials, book of instructions, and a fiber carrying case.

A Handy Gasoline Gauge.—The Connecticut is a little instrument to be screwed on the dash in front of driver and indicates the amount of gasoline in the tank by a column of colored fluid ascending and des-

cending between a graduated scale. In principle it is simple, the gauge consisting of a reservoir to which is connected a small pipe about one-eighth of an inch in diameter, the other end of the pipe being connected to a proportioned tube which

CONNECTICUT TANK GAUGE.

passes through the top of the tank. In the gauge proper there is a glass tube which passes down to the bottom of the reservoir in the gauge. When the fluid in the gasoline tank is raised it creates an air pressure in the tube mounted therein, which is transmitted to the surface of the liquid in the gauge reservoir. As the supply of gasoline decreases the air pressure diminishes and a corresponding fall in the liquid ensues. The gauge is very easily fitted, the connection to gasoline tank being a semi-flexible seamless drawn tube one-eighth inch diameter soldered into tank. It will be noted that no gasoline passes into the gauge itself, consequently there is no danger from this source.

Handy Electrical Contrivance.—The American Electrical Novelty Manufacturing Company, 304-8 Hudson street, New York, has produced an ingenious and simple battery wire connector, the nature of which will be readily understood on reference to the accompanying right-hand cut.

To attach the wire is but a moment's work; for it to disconnect owing to vibra-

SELF-ADJUSTING WIRE CONNECTION

tion or road shocks, is practically an impossibility. Several size Ever Ready cells are made. Style K, 3 x 7 inches, of 27 to 30 amperes, and style J, 2 1-2 x 6 inches, of 22 to 25 amperes.

German Ball Bearings.—Annular and thrust bearings manufactured by Fichtel & Sachs, Schweinfurt A. M., Germany, will occupy space 27 at the Madison Square show. F. & S. bearings have a high reputation in Europe, being employed by such firms as Daimler (Mercedes), Darracq, Fiat, Isotta Fraschini, Adler, Opel, Benz, English Daimler, Napier and Wolsley. Though only recently introduced into the States, they are being extensively adopted by American constructors. The Fichtel & Sachs annular ball bearing consists of two concentric rings of races, grooves in the races, steel balls running in the grooves, and a cage (made in two sections and

displacement, the depth of the race grooves is much greater than the depth of the oblique cuts, and every ball is enclosed in a separate pocket, so that no harm can result from the accidental breaking of one.

An English-built Speed Indicator.—The speed indicator manufactured by S. Smith & Son, Strand, London, and enjoying a high reputation in England, France and other European countries, are now being offered to the American public. A very complete series is produced by the firm, ranging from the simple speedometer indicating only speed and mileage, to more elaborate apparatus, combining clock, speed, trip and season mileage, and electric indicator for communicating orders to driver. This latter is a particularly handsome combination and does credit to any dashboard. A great feature of the instrument is the specially light construction made possible by a new method of springing the governor. By this arrangement the instrument can be supplied in standard form, it only being necessary to alter the position of the pulley upon the metal disk attached to the wheel to obtain the necessary adjustments for the varying sizes of wheels. The speedometer is a most satisfactory one to clock, for it is practically suitable for every size of wheel and every make of car without alteration. During November, 1906, Messrs. S. Smith & Son received orders for 1,671 of their instruments. Their present output is 120 per week, but it will be increased to 200 shortly.

ratchet bar is of strong steel with milled teeth. A lifting capacity of two tons is guaranteed. By reversing a cam at one side of the jack with the fingers a reverse action is obtained that permits the axle to be lowered by an easy pumping action of the handle. The entire out-

F. & S. BALL BEARING.

permanently joined together) containing and positively separating the balls equidistant and keeping them in perfect alignment. The bearing is of steel of an exclusive analysis. Each bearing has a complement of more balls than will fill one half its circumference. The rings, or races, are each provided with obliquely cut grooves which, when brought into proper relation, will permit of the introduction under pressure of additional balls. When working under a strain the balls cannot escape from the race in reverse action to their introduction, for the circumferential action of the balls is opposed to the direction of one of the oblique grooves, the permanent alignment provided by the cage prevents

Enlarged Standard Jack.—The No. 1 Standard automobile jack has been greatly improved for the season of 1907 by an increase of nearly one-half in the size and by a change in the ratchet action. The area of the foot or base has been increased to nearly double the old size, so that there is no difficulty in making the jack stand up, and the yoke has also been enlarged to 2 1/4 inches wide, so that it will hold the axle securely. The Standard is a single-acting jack, the ratchet mechanism working only on the down stroke, when the operator can bring all his weight to bear upon the handle. A change in construction makes the leverage much more effective, so that the heaviest car can be raised without undue exertion. The

IMPROVED STANDARD JACK.

put of the No. 1 Standard jacks, which retail at \$4.50 each, is controlled by the Motor Car Equipment Co., 55 Warren street, New York City.

RECENT INCORPORATIONS.

Garrett Automobile Company, Garrett, Ind.; capital, \$10,000. Directors, Charles J. Rollins, Charles Colgrove and William Mitchell.

Motor Car Renting Company, Boston, Mass.; capital, \$10,000. President, F. E. Litchfield; treasurer, E. S. Litchfield, Brookline.

Newton Garage and Automobile Company, Portland, Conn.; capital, \$10,000. President, N. Clifford; treasurer and clerk, E. C. Verill, Portland.

Portland and Rockland Automobile Company, Portland, Conn.; capital, \$10,000. President and treasurer, J. A. Lester, South Thomaston.

A. B. C. Auto Buggy Company, St. Louis; capital stock, \$40,000. Incorporators, A. B. Cole, Robert L. Steele, Jr., and F. F. Stevens, 150 shares each.

Austin Agency, Inc., Boston, Mass.; capital, \$10,000. To make and sell autos and vehicles. President, F. E. Litchfield; treasurer, E. Litchfield, Brookline.

The Rivers-Jacoby Automobile Company of Toledo, Toledo, O.; capital, \$25,000. Directors, W. E. Jacoby, A. F. Nicklett, A. D. Rivers, C. G. Smith and E. E. Davis.

The Citizens' Motor Car Company, Cincinnati, O.; capital, \$100,000. Incorporators, Briggs S. Cunningham, H. E. Breneman, J. M. Richardson, J. E. Thomas, and Robert Ramsey.

Southern Automobile Company, Limited, New Orleans; to deal in and repair automobiles; capital, \$15,000. Incorporators, L. Stortz, Jr., George C. Escoffier and Solomon C. Meyer.

Auto Appliance Company, East Orange, New Jersey; capital, \$150,000. To manufacture motor vehicles, etc. Incorporators, C. L. Beck, C. O. Geyer and F. O. Ferguson, East Orange.

Model Automobile Company, Peru, La.; capital, \$50,000. To manufacture automobiles, automobile parts and supplies. Incorporators, Albert Kittner, Milton Krauss, W. S. Muer and H. P. Sullivan, directors.

Economy, Efficiency and Safety

¶The NATIONAL Gasoline Storage System is the most economical, because it entirely eliminates evaporation and waste of gasoline. ¶It is the most efficient because the NATIONAL Pump discharges gasoline at every movement of the crank, and is always ready to operate. ¶It is the safest, because it meets ALL of the requirements of The National Board of Fire Underwriters.

THE AUTOMOBILE

VOL. XVI.

NEW YORK—THURSDAY, JANUARY 17, 1907—CHICAGO

No. 3

AN INDUSTRY'S PROGRESS AS TOLD IN ALAM SHOW

THE second show of the Association of Licensed Automobile Manufacturers, and the seventh affair of the industry in Madison Square Garden, tells unmistakably, substantially, and artistically its own story of gratifying and unexampled progress. It is an exhibition that bears all the imprints of a successfully established in-

dustry—an exhibition that yet betrays the earmarks of youth and still gives evidence of its lusty growth. It should be mentioned here, thus early in the report of the A. L. A. M. show, that its experienced pioneers do not compose all the automobile makers of the country, for scarcely a month ago the American Motor Car

PRESS AGENT JERVIS,
Who "painted [the] lily" and
"gilded refined gold."

Manufacturers' Association supplied the greater part of another notable exhibition of the industry which the Automobile Club of America conducted in the Grand Central Palace. In realizing the magnitude of American automobile manufacture, the total must be that of two shows held in the two largest buildings of the metropolis; and in this connection comes the wish for a mammoth structure that would house all the makers and present the American show in such manner that it would surpass the famous Paris Salon, with its elaborate

decorations and roomy spaces. And the Salon includes the makers not alone of France but of Italy, Germany, England, Belgium and Switzerland; therefore the American magnitude excels that of any other single country.

New York has had six automobile shows in the Garden before, but the A. L. A. M. committee, consisting of Chairman George Pope, M. I. Brock, C. R. Mabley, and Secretary M. L. Downs, completely met the metropolitan appetite which had been whetted by the previous events of like character. Great things had been promised for this 1907 affair, promised early in the season before its predecessor had totally faded from view, and so something which would totally eclipse everything that had gone before was looked forward to.

Nor did the realization fall short in any detail of fulfilling expectations. Promptly at 8 o'clock, Saturday night, the show, which had been open for two hours before that time—if the number of visitors interestedly taking in the details of the many cars exhibited may be taken as a criterion—was formally thrown open to the public. Nearly an hour later, to add éclat to the occasion, came the representatives of foreign powers, among them being Baron Mayor des Planches, the Italian Ambassador; M. de la Fosee, counsellor of the French Embassy; Lieutenant Commander de Blanpré, naval attaché of the French Embassy, and M. de Thal, the Russian Ambassador. But the thousands who had come to pay homage to the Automobile and who were content to take their turn in slowly circulating around the all too narrow aisles in order to get an opportunity to see the different exhibits, did not have to be told that the show officially was "open." Their arrival had opened the exhibition.

Despite the gloomy and rain-soaked condition of the outer world, the Garden was a picture of many colors that proved too strong a drawing card for the weather man to counteract, and thousands poured in through the large double doors—hesitated momentarily to fully take in the details of the magnificent conception that towers twenty feet above the floor, and went either side of it to fulfill the purpose of their mission, the splashing of the fountain forming an accompaniment to the myriad footbeats. And the sight that greeted the eye was one of completeness in detail, one that lacked nothing to make it complete, not a gap here and another there, but long lines of polished chassis and complete cars, with nothing to indicate their identity but the inconspicuous signs of their makers above them, the cars and the panorama of Swiss scenery behind them blending so completely as to make it seem as if the cars were in their natural element and lacked nothing but drivers. So far as the crowd itself is concerned, it only remains to say what has been said of the attendance on opening nights for the past two or three years—it was a greater and more enthusiastic crowd than has ever before lent its aid to inaugurating an automobile show.

If the success of such an event is to be judged from the beauty of the picture presented by the tout ensemble, and by the size of the aggregation that comes to view it, then indeed is the "Seventh Annual Show" the greatest of its kind, for neither in

the elaborateness of its conception nor in completeness of advanced preparation, despite the vast amount of work that had to be condensed into a very short space of time, was there anything left to be desired. Saturday night was not a sort of preparatory view of what the show would be like later in the week, as it has been in former years, but it was a revelation of the complete whole, uncovered as it were by a sweep of the hand. The background of bare walls and columns which have formed the foundation of the setting for the automobile for seven years past are entirely lost on the present occasion in the profusion of decoration. From the thousands of yards of soft yellow that shut out the girders of the building from view, and behind which a myriad of incandescent lights twinkle, to the smallest section of canvas depicting Alpine scenery that serves to cover the walls, not a spot of the bare brick and iron have been left uncovered, the whole blending softly at every turn into a huge panorama that is complete from whatever point it may be viewed. And the realism is greatly enhanced by the effective use of rustic decorative work, which, though employed in large quantities, is as a whole subsidiary to the scheme of ornamentation and does not intrude itself upon the attention.

As for the cars themselves—and after all they constitute the jewels for which this extremely elaborate and ornate setting has been prepared—it is difficult to know where to attempt to undertake a description of the achievements they represent. Occupying the main floor of the large arena are the products of firms whose names have been closely linked with the progress of the automobile in this country ever since such a thing as an automobile industry had its inception—in fact, for a long while they were the American automobile industry. Grouped with them are a number of Europe's most noted makers, so that a comparison of the flower of automobile productions of standards obtaining on both sides of the Atlantic may readily be made—a comparison, by the way, that redounds to the credit of the American maker. Here, in all, are spread out no less than forty-seven groups of cars—the products of some of the largest and best-known factories in the world—in short, a very large portion of the real bone and sinew of the automobile industry the world over. The demand for space in which to show those same products has become so pressing that even the heavy vehicles are no longer confined to terra firma, but some have mounted heavenward to an elevated platform, specially constructed for the purpose, despite their bulk and avoirdupois. Where formerly the accessory maker held sway the great spread of cars is continued.

On the level below the main floor, the horseshoe circuit of the basement, which erstwhile dingy abode of bare brick walls and otherwise uninviting appearance has been transformed so that even those most familiar with it would fail to recognize it at first glance. Holland scenes form the basis of the decorative scheme, and they cover the long walls in panels stretching from floor to ceiling.

In the exhibition hall still another plan of decoration has been carried out, and here the electrics hold forth in all the stately dignity of their luxury of furnishing and lack of mechanism to intrude itself on the vision.

Above them in the concert hall the scene is again transformed, as are also the subject of the exhibits for which the new color scheme

THE MADISON SQUARE GARDEN.

forms a setting. Here an oriental blending of blue, red, and green forms a background for dozens of exhibits of the materials that go to make a car.

Above the elevated platform that has been pressed into service this year to accommodate an increased number of cars, and separated from it by but a step or two, is the mezzanine floor that holds the first of that seemingly endless array of exhibits of accessories. Tier above tier they stretch around the entire circuit of the large building in uninterrupted rows. Taken all in all, it is an achievement in the successful accomplishment of which its sponsors may well take pride.

As a standard by which to judge the success of the show from the financial point of view, it may be added that not even the call for a double admission price, coupled with the uncertain weather which continued over Tuesday, was sufficient to cause any marked falling off in the attendance. And that is saying a great deal, for, before the lights are turned on, the Garden is a gloomy enough place on a dark and muggy midwinter day. Still the visitors came to see and admire, and in the evening there was the same crowd of interested spectators taking in the details of the many cars and circulating among the numerous lesser exhibits. Whether the doubling of the admission price had the desired effect of thinning the crowd down to those who numbered a greater proportion of prospective purchasers than has been the case on ordinary nights, as was presumably the intention of the management in making this innovation, cannot be said, but, judging from appearances, it did not have an unusually perceptible effect in lowering the attendance.

NEVER BEFORE HAS MADISON SQUARE GARDEN BEEN GIVEN SUCH AN ELABORATE DRESS AS FOR THE SECOND SHOW OF THE ASSOCIATION OF LICENSED AUTOMOBILE MANUFACTURERS.

THE AMERICAN CAR AS PRESENTED BY THE SHOW

By C. B. HAYWARD.

AMERICANS are prone to exaggerate the merits of anything that bears the stamp of the eagle; much given to over-vaunting their prowess and their achievements in every line of endeavor, whether it be one they have had long experience in, or something of recent adoption. Such is the trend of foreign opinion of the things that are said of the products sent broadcast from

EXHAUST SIDE NEW WINTON 40 HORSEPOWER MOTOR.

this country to other markets. Thus the American maker is more than proud of the American automobile and with good reason, while the foreigner, on the other hand, is given to belittling its design, its appearance, the materials that enter into it, and its capabilities, usually concluding with the consoling statement that, in the fullness of time, the American maker will learn how to build automobiles. Truth is seldom a matter of extremes and the present is no exception to the rule, so that the status of the American automobile is neither that of the invisible pinnacle of unapproachable superiority, nor the low level of mediocrity. In view of the stock consolation offered by alien and not wholly disinterested critics, it may well be asked: Has the American maker learned to build automobiles?

With the brave showing spread out in the Garden during the present week, it has not been difficult to formulate an answer. Giving all due credit to the sources from which he has borrowed, and at the same time admitting candidly that he was following the wrong road for some time at the outset, the American maker is certainly entitled to say that he has not alone learned his lesson, but outgrown his teachers. Starting with the very foundation of every mechanical construction—the materials—it does not require any lengthy explanation to impress upon the most casual of observers that this most essential requisite of successful automobile building has been given the attention that its importance deserves and that the metals which enter into the make-up of the American automobile are those which long investigation in the science of metallurgy has shown to be the best adapted for the purpose. The steels that enter into the frames, axles, transmissions, and minor parts and the iron used in casting the cylinders have been selected for those qualities which analysis and experience have shown to be requisite if that high degree of efficiency and smoothness of running, which are the aim of every builder of high grade cars, are to be attained.

Detailed Execution and Workmanship.

America has long stood preeminent as the home of metal-working machinery of the most advanced type, as well as methods of operation and shop practise best calculated to produce the desired

result, so that in taking up the manufacture of the automobile the domestic maker was but turning his talents to a rôle in which he was already well-versed. It is a matter of common knowledge that large quantities of machine tools of American origin are employed in the manufacture of cars abroad, so that in this respect at least, the American maker had the start of his over-sea competitor from the beginning. To realize that he has fully profited by his advantage, it is only necessary to note the quality of the workmanship that characterizes the American car as represented in the show—not the polished exhibition chassis which is a mechanical work of art requiring several times as much pains and labor as are expended on the ordinary stock car for its execution, but the car which is delivered to the purchaser. Clean, smooth cylinder castings, free from flaws of any kind, accurately turned flywheels, close-fitting gear and crankcases—an ensemble of painstaking design that would have elicited unbounded admiration could it have been suddenly revealed a few years ago alongside the work of that day, but which in the meantime has come to represent a standard of finish common to even the lowest-priced cars, so that its prevalence no longer arouses any comment.

This is but the first impression of a general observation—looking a little further is productive of revelations that only the experienced eye, familiar with what has gone before, can read aright. Slipshod methods have gone down before the steady march of improvement, and what were at best but makeshifts borrowed from past experience in which conditions met with in automobiling had played no part, have had to give way to methods of accomplishing the same thing in a manner specially designed to effect it in view of the service it will be called upon to render. The cotter pin, for instance, was an effective fastening on small parts not subject to unusual stress or vibration, and for that purpose it found a place on the automobile wherever it could be employed. As an example, it may be cited that the old-time valve spring retainer was a split or cotter pin and a common iron washer taken from the stock of the hardware dealer. Now a specially designed retainer with a recessed face to hold the spring properly constitutes a form of fastening, that it takes but a glance to see was made to do the work required of it. The thought of a camshaft with eight integral cams would have overcome the average maker a few years ago; its cost would have been prohibitive and the necessity of such refinement in manufacturing methods, in order to obtain greater accuracy and durability, would have appeared to be a waste of money. Cams were made separately and pinned in place; now the shaft and its cams are a single piece and the former are ground to a minute fraction of an

COLUMBIA 40-45 HORSEPOWER MOTOR FOR 1907.

inch, after which the faces are case hardened. Instances of the same nature might be multiplied indefinitely.

Standards of Motor Design.

It is probably useless to expect that any large body of designers will ever be thoroughly in accord on any subject involving so many opportunities for detailed differences as that of motor design, though years of experience have resulted in evolving a type of construction that is followed so closely in such a large number of instances as to warrant being termed current practise in this respect. Take the matter of cylinder casting, for example, and all the cars in the show may be immediately divided into two representative groups, those adhering to the twin type and those favoring the independently cast cylinder. There are so many things to be said in support of either method that when the advantages and disadvantages are to be weighed in the balance it becomes extremely difficult to differentiate between them. The merits and demerits being thus evenly apportioned, the number to be found ranged on either happens to depend upon which was chosen in the beginning. The matter of valve-placing is another and probably the most prolific source of difference in the case of the different designers. It would be difficult to state just what proportion of them adhere to the opposite disposition of this important essential of the motor, using deep pockets in connection therewith, and how many favor the concentration of the valves on the same side, without taking a detailed census of the cars shown. The matter is further complicated both by those types in which both valves are centered in the head and the entire interior of the cylinder is machined, which is a characteristic of air-cooling practise, and those in which the exhaust valve is placed in the center of the head and the inlet retained at the side.

This, of course, is still further influenced by the type of valve-operating gear employed, and though the majority of designers have retained what may best be termed the standard method as it is represented by far the greater of makers, there is a tendency away from it. This is the direct lift, or push rod, which is a feature of probably 90 per cent. of all the cars shown, whether American or otherwise. In some instances, it has been modified by the interposition of a lever carrying a roller between the cam and the push rod end in order to eliminate the side thrust produced by the cam, particularly that of the inlet with its elongated profile. As a direct deviation from it there is what amounts to a return to one of the oldest standards—that of the rocker arm or walking beam, long a feature of the vertical type of stationary engine, as well as that of the superimposed type in which the camshaft is placed on top of the cylinders instead of along their base. If a leaning there be toward one or the other, where the matter of valve disposition is concerned, it would probably be found to be toward the practise of placing them on the same side of the cylinders owing to the simplification brought about by the elimination of one of the camshafts, although the same end has been attained by the adoption of the overhead type of operation whether by means of rocker arms or directly from a superimposed camshaft, the opposite disposition still being retained and valve pockets done away with. The principle of offsetting the cylinders on the crankcase has come in for considerable attention though its actual advocates are not numerous.

Status of the Motor Accessories.

Though seemingly numerous at first glance, these may be readily divided into the three essentials of carburetion, ignition, and lubrication, and whether taken singly or collectively they are essentials upon which the majority of American cars reveal more of accord than difference. This is true of all three, though in the matter of carburetion there is probably more uniformity than in the other two combined. With but one or two prominent exceptions the water jacket has been considered unnecessary, so it may safely be stated that as a general rule the modern carbureter on the American car is not of the water-jacketed type. In many cases warm air is led from around the exhaust to the vicinity of the carbureter, though the instances in which even this is not considered essential, are far from few.

PIERCE GREAT ARROW FOUR-CYLINDER MOTOR.

Despite the vogue given the multiple jet type on the other side, which in the end proved short-lived, it found no imitators here, the use of single jet representing practically universal practise. One deviation from this, however, is to be found in the employment of two carbureters of different sizes, fed from a common float chamber, one being employed when the engine is run at reduced power and the other at full load, the same throttle lever actuating both and keeping the larger closed until the smaller is fully open. Another innovation to be found in a carbureter of special design is the introduction of a light fanwheel set directly in the path of the mixture, the suction of the engine causing it to rotate at high speed, mechanically agitating the fuel and causing the gas and air to combine more homogeneously, as well as preventing the introduction of fuel in a liquid or semi-liquid state into the cylinder. Where the prevailing type is concerned the chief difference noticeable is in the form of auxiliary air valve employed, a few using a piston while in the majority a spring-controlled diaphragm is employed.

Ignition and Lubrication Practise.

Where the first of these essentials is concerned, advancement on the American car has been largely governed by the selling price of the latter. It is a matter of common knowledge that no matter how perfect the ignition system may be, it is subject to derangement and that the best insurance lies in its duplication, but as this involves an expenditure disproportionate to the cost of many of the lighter types of cars, its adoption was not possible

EXHAUST SIDE ROYAL TOURIST 45-HORSEPOWER MOTOR.

THE NEW STEVENS-DURYEA 35-HORSEPOWER "LITTLE SIX."

except as an extra. It takes the form of a magneto system on one side, and an accumulator and coil system on the other, each with its own independent connections throughout as well as separate sets of plugs. This is modified in some instances by dispensing with one set of plugs and in others by employing the same coil as used on the high tension magneto in connection with a special mechanical timer to commutate the battery current which is distributed to the plugs through the high tension side of the magneto. In practically every instance where duplication has been practised both sides are high tension, though there are instances extant in which both high and low tension ignition is employed on the same car. Painstaking attention to the details of coil, accumulator and high-tension cable manufacture together with the extended experience had in the needs of this essential of the car have brought the ignition system of the American automobile to a point where with ordinary care and attention it is no longer the cause of a fraction of the annoyance that it originally gave rise to in the maintenance of a car.

To judge from a census of the motor details of the cars shown, the mechanical type of force-feed lubrication is practically a standard, the advocates of pressure or other types of oil feed being very largely in the minority. The number of independent feeds employed range all the way from two to 14, in some only the most important bearings having a direct oil supply carried to them, while in others even minor bearings ordinarily lubricated by splash are likewise taken care of. The most important exception to this type of lubrication is to be found in the pump-circulating system which is represented by several well-known advocates of its extreme simplicity and reliability, which to a very large

CORBIN 24-HORSEPOWER, AIR-COOLED MOTOR FOR 1907.

extent take the matter of responsibility for lubrication out of the hands of the driver. Though differing in individual instances the system consists essentially of a liberal supply of oil usually carried in a tank in close proximity to the motor, an oil pump and a well at the lowest portion of the crankcase, partitions usually being employed in the latter to maintain the same level under each piston and connecting rod. The overflow from each compartment drains back to the well and after passing through fine screens is again circulated by the pump, this action being continuous as long as the motor is in operation.

Transmission, Drive, and Running Gears.

Starting with the first step in the transmission of the power from the motor to the rear wheels, it is noticeable that the tendency toward the adoption of a form of clutch not possessing the disadvantages of excessive inertia and momentum which are inseparable from the use of a clutch of large diameter and weight, has favored the use of the multiple disk type which is now represented to a very large extent on the American car. Owing to its compactness it has made the combination of the clutch and change-speed gear box an easy matter and this practise is noticeable in numerous instances. The size of the latter has been reduced by the more general adoption of the selective method of gear-changing so that instead of the frame being almost filled with mechanism from side to side at this point as was at one time the case, there is now comparatively little, and this is even more noticeable in the case of those cars in which the change-speed gear box and the bevel drive have been combined at the rear axle in a unit, little if any larger, than that formerly necessary for the differential and bevel drive alone.

Where the final link is concerned, it is obvious at a glance that the limit of power to which the shaft drive is applicable has been steadily increasing from year to year so that now all but the cars of the highest powers employ the propeller shaft and live rear axle, with but one or two exceptions. On heavy cars using double side chains, more attention has been devoted to the latter in order that the difference in the operation of the two types due to dirt and wear on the chains should not be so noticeable on the score of noise. To this end, chain cases are now being provided so that the chains may be kept properly lubricated and away from the deleterious influence of the mud and grit of the road. Not less important than the application of the power itself is the means of bringing the car to a stop when necessary and it is noticeable that with the increase in power much-needed attention has been devoted to the braking equipment. It has become very general to center this on the rear wheels, usually taking the form of internal expanding and external contracting brakes applied to a special drum bolted to each driving wheel, instead of causing the braking effort to act on some part of the power transmission nearer the motor, as was formerly the case.

Wheelbases having reached a point where further increases seem impossible, the use of the channel section pressed steel frame has become practically universal. With the frames of lower grade materials, or of built-up types common a few years ago, the weight in the case of the average car would have proved prohibitive. There are still a few exceptions who cling to former methods or special types of construction of their own where this part of the car is concerned, but they are so largely in the minority as to be overlooked by the casual observer unless special attention be called to this feature. Practice where suspension is concerned has undergone little if any change, although it would seem as if the use of the full elliptic spring had found a greater number of advocates than formerly. There are in addition, scattering instances of the employment of the three-quarter spring on the rear as well as the transverse platform type. Wheel diameters have undergone a very general increase, although the largely increased power of the average American car is likewise responsible for this, the small wheels formerly employed looking totally disproportionate to the remainder of the car. Thus wheels have advanced by jumps from 30 inches, to 32, 34, and 36 inches, the great majority now being of the 34-inch size.

WAGNER'S DARRACQ, SHEPARD'S HOTCHKISS, TRACY'S "LOCO."

HARDING'S HAYNES AND LE BLON'S THOMAS.

AS THE SHOW LOOKS TO A NEWCOMER

By W. F. BRADLEY.

READED in the atmosphere of the Grand Palais, with stage master Gustave Rives as instructor in the art of gorgeous decoration, one feels a strange incompleteness on entering Madison Square Garden for the first time. It is, perhaps, akin to the sensations of a Parisian *belle* on being deprived of her richest toilettes, or of a man about town on losing his *maitresse*. It is useless to argue that neither one nor the other fulfills any useful purpose, and that a chassis on a plain wooden floor is no less a chassis and is much more conveniently examined than the same machine lost among fairy-like decorations costing twice the value of the exhibit. Rives has elevated us—or lowered us, according to the viewpoint—to expect of an automobile show a spectacular display equal to that of the National opera house on a gala night.

Not even the black uniformed ambassadors, flanked by their Swiss guards, strolling through the hall with more dignity than President Fallières and his escort of fussy policemen; not the keen American salesman who has got the finest machine the world has ever seen, and who lets you know it; not even the fair ladies, clad in the best that the Rue de la Paix ever exported, can fill the void. But Rives had he been here would have had a task in making the moderate-sized Garden equal the big Palais.

* * *

"Hello, Wagner, how goes it?"

"O, vous savez, je m'ennuie terriblement ici. They are all right, these Americans; they all come to shake hands with me and I don't know half of them."

"No, I won't have a drink, thanks."

"They give me so many here that my stomach has all gone wrong. This American food, too, you know, isn't bad, but it isn't worth a good plate of French soup."

"They are getting the Cup out," said the Vanderbilt hero, nodding towards a big polished wooden box. "We brought it over with us on the *Bretagne*. It hasn't got my name engraved on it yet, but that doesn't matter to me."

"Will you take your clothes off and sit down here, Mr. Wagner?" interrupted an interpreter in broken French.

"La barbe" (whiskers), said the Frenchman. "I'm not here as an advertisement."

"Those interpreters get on my nerves; I speak as slow as possible, yet they can't understand me. If only there was somebody to speak French to."

"Just sold a car," yelled a round-faced joyous Darracq man,

who explained that he had gone into the automobile business because his legs were too short for cycling. "Tell Wagner that."

"Bon," replied Wagner, "you'll keep a commission for me; I won the Cup."

Close by, on a separate booth, stood the Darracq, the Hotchkiss, and Tracy's Locomobile racer, in charge of an attendant dressed like a Salvation Army man.

"It's the machine that won the cup," said Wagner; "we brought it with us, and are going to run it at Florida, Vevet and I."

"The race don't interest me any more than the show. We shall only run long distances. It's no use trying short spurts against steam. These beach races cannot be compared with the Vanderbilt. No skill is required. You simply open your engine out and let her run."

"Bonne chance, tout de même."

"Merci, au revoir."

* * *

A few yards further on, at the end of the foreign section, stood the Dietrich Vanderbilt racer, just arrived from Paris. Duray, the intrepid, had been unable to accompany it, and the racer will return to France without making its exhaust heard in the land of the Stars and Stripes.

On the opposite side of the hall, peacefully reposing against a background of Swiss mountain scenery were two American racers; the Thomas on which Le Blon displayed his skill, and the plucky little Haynes, which matched itself against the more powerful flyers.

* * *

To European eyes the American exhibits at the Garden Show indicate enormous activity, for which in two cases out of four, an adequate return has not been obtained. Local conditions have, of course, to be taken into consideration, and objections which hold good in Paris, would fall to the ground in New York. Gracefulness of design, compared with French and Italian productions is woefully lacking in many of the American cars. Front wheels are flush with the radiator; rear seats are well astern of the back axle and appear to have been placed to give the maximum amount of discomfort. On the other hand a number of makers have produced vehicles, which, for harmony of lines, rival anything sent from France. Light two-seated runabouts of sufficient power to travel at a rapid clip over any roads are a fine class. Speaking generally, there is more inventive genius and more variety of design—it is not necessarily all good—at Madison Square than at the Paris Show.

DIPLOMATS INSPECTING THE EXHIBITS.

Baron Edmundo Mayer des Planches, the Italian Ambassador, with Col. George Pope and C. R. Mabley of the Show Committee, and two Italian Embassy attaches.

There is not a wholesale copying of European flyers, as some have tried to make us believe, but rather an attempt on the part of each manufacturer to work out his own salvation. Makers of high-grade touring cars follow more or less closely on European types, but outside these, are numbers of distinctly American cars. Air-cooling, a type practically unknown in Europe, has been brought to a high state of perfection, and there is no doubt that some of the models on view would cause a sensation in France.

Planetary gear, overhead valves, copper water jackets, wooden side frames (on air-cooled cars), flywheels in front, and full-elliptic springs, are all, more or less, American features.

Brakes too often are of the external type, very lightly constructed. On the generally lighter chassis built here, they should, however, be quite up to their work. Very few drop frames are seen, though in Europe this type is commonly employed. Propeller shaft drive appears to be more generally adopted here than in France or Italy, where the practice still is, despite a slight ten-

dency this year towards shaft drive, to use chains for high and moderate power cars and shaft only for small machines. Judging from the bare chassis many shafts are unnecessarily inclined.

Excellent examples of coach work are shown and it is not surprising that imported chassis are frequently fitted with American-built bodies. A number of landaulet and limousine automobiles of American construction vie with anything produced in France, and there is one example of an inside steering limousine body equal to any imported article.

INCREASED PRIZE LIST FOR BALLOON RACE.

In addition to the Gordon Bennett Cup to be competed for at St. Louis, on October 19, several prizes of lesser importance will be offered. The cup winner will receive \$2,500 from the citizens of St. Louis, to be taken either in cash or converted into plate. The railroads running into St. Louis offer \$1,000 to the aeronaut making the second best record in distance traveled; John F. Hugent offers \$750 for the third best distance, and J. M. Schroerer offers \$450 for the fourth best record.

It is probable that the Aero Club of America will give a separate cup to the aeronaut who remains in the air the greatest length of time, while the German-born citizens of St. Louis have promised a special cup to the representative of Germany who makes the best record, irrespective of the showings of the other entrants. Frank S. Lahm has sailed for Europe to solicit entries for the race and represent the A. C. A.

A PACKARD ARRIVAL.

A FINE REPRESENTATION OF PACKARD "THIRTIES."

GREAT ARROWS WERE PROFUSELY DISPLAYED HERE.

SOME IMPRESSIONS OF THE LICENSED SHOW

By VICTOR LOUGHEED.

THE 30-35-horsepower Simplex presents a comparatively radical deviation from standard practise in that the cylinders are jacketed with sheetiron jackets, held in place with a multitude of small screws. In this way, all problems of core-sand removal are done away with, and the weight is reduced considerably.

The single C. G. V. chassis on view is one of the number to introduce this year for the first time, the scheme of enameling instead of polishing as an all-over finish. The practical advantage is that rusting is done away with and with it the possibility of injury to clothing from contact with the grease generally used as a protection for the high polish. The chain adjustment is of the eccentric type, which by rotation forces back the radius rods and with them the rear axle. The chain boot used on this car seems to meet with general approval.

On the Royal cars, there appears a novelty in the distance rods used, which are attached at their forward ends to the frame sides by means of a regulation ball joint, allowing free movement laterally as well as vertically, and providing takeup on the wear that at this point is so apt to produce injurious rattling and pounding.

One of the unusual minor features of design, which, though not altogether new, nevertheless causes comment, is the Packard system of controlling the reverse of a sliding gear system by a separate lever, thus making it practically impossible for the reverse to be confused with any of the forward speeds.

Though the large car of the Northern line bristles with novel features, comparatively few of these features are materially different from their counterparts at the last show. The pneumatic clutch and brakes, the use of the two-to-one gears as the circulating pump, etc., are the same as they were, but the extraordinary rear springs are sure to halt the casual observer. They are 60 inches long, and are supplemented by a transverse platform spring shackled to their rear ends.

An interesting detail that appears for the first time on the 1907 Winton cars, of the more powerful type, from which the well-known pneumatic control is eliminated, is the peculiar inter-connection between the throttle pedal and the throttle lever. This inter-connection takes the form of two geared semi-circles, each like half of a bevel gear, between which there is held a floating

bevel pinion. By this means, if the bevel gear attached to the pedal is in any given position, a movement of the lever will instantly act upon the throttle through the bevel gear attached to it, its fellow constituting a fulcrum. Besides this novelty, the actuation of both valves to each cylinder by a single spring placed between them attracts attention. The transmission brake is equalized by a short whiffletree device, following common practise, but a new idea is shown in the method of equalizing the application of the rear-hub brake through means of a long transverse torsion rod, which readily twists enough to produce the compensating effect.

The Lozier people are among the newcomers to the disk clutch idea. Their show chassis is particularly well finished, and though little about it is radical almost everything about it is interesting. The Lozier commutator possibly is the most striking feature, it

PLAN VIEW OF THE 40-H.P. LOZIER MOTOR.

being mounted upon a vertical pillar and rotated in a horizontal frame by a bevel gear on one of the camshafts. There is only one rotating contact, and this consists of a wire brush which can be removed and replaced in less than a minute, making it practically impossible for an irremediable fault to occur. Chain boots are applied on this car, and the filling nozzle on the rearwardly placed fuel tank projects behind the car at a convenient angle and contains within it a simple gauge for showing at a glance the quantity of fuel contained.

Interest at the Cadillac stand centers around a sectioned working model of the new 20-24-horsepower four-cylinder engine. This model is driven by an electric motor, so that all of its parts and functions, even to the spark within the cylinder, occur as nearly as possible as they would in an operative car. This same 20-24-horsepower car departs from previous Cadillac practise in the use of a sliding change-speed gear, of selective pattern, affording three speeds forward. The show chassis is enamel finished.

Though wooden frames have been Franklin practise ever since there were Franklins, the polished and varnished frame on the show chassis will undoubtedly be the first means of impressing many casual motorists with knowledge of this authoritative use of this construction. Another detail of interest is the modification in the operation of the progressive gear shift. By very trifling changes in the form of the sector notches it is made impossible to go in either direction from the intermediate speed without unlatching, or from the low to the reverse without unlatching, though all other shifts require nothing but a push or pull on the lever.

The Pierce cars maintain their high prestige without slavish adherence to accepted forms, and still display the change-speed gear lever on the steering pillar, are equipped with the interlocking clutch control, and have irreversible steering. The brakes are equalized by whiffletrees wider than the frame, through slots in which they work. A somewhat surprising departure is the elimination of the subframe, Pierce engines now being carried on transverse manganese bronze supports, bolted directly to the main frame sills.

The inclined engine of the newest four-cylinder Knox chassis, permitting, as it does, a perfectly straightline transmission through the crankshaft, the gear-box, and the propeller shaft to the rear axle, seems the best of good engineering, as also does the very ingenious three-point support. Change-speed gear and engine both are mounted upon a massive though light aluminum casting, with an opening in it for the flywheel. The casting is held at the rear by two side arms, while at the front it is borne

upon an aluminum bronze cross member by a trunnion permitting slight movement. The irreversible device in the steering gear is interesting because of the quintuple thread and nut.

The star of the Peerless stand is the "Berlin body," which is not like anything ever heretofore seen in this country, but nevertheless looks good. It provides perfect protection for driver as well as for the other passengers and is a most imposing appearing conveyance. R. B. F. annular bearings are used, and a novelty is shown here in that regular lubrication is provided for these bearings by means of small oil boxes and individual leads—a refreshing attention to detail, in view of the more or less current belief that ball bearings don't particularly need lubrication.

The Thomas "Forty" and the Thomas "Sixty" vie with each other in their claim upon popular attention, and are especially worthy of thorough examination, because of the high quality of construction throughout, which absolutely follows the best points of foreign practise, with not a few domestic ideas that take rank with the best of the foreigners. A particular instance of this is the clutch.

Two chief points distinguish the new Pope-Toledo cars—one, the actuation of both valves to each cylinder by a single push rod; and the other, the application of Hess-Bright bearings to the crankshaft. Besides these there is the new multiple disk clutch, the placing of both valves in the cylinder head, and a number of features of minor interest.

Small as has been the growth of the two-cycle idea among the more conservative manufacturers, there is no denying that the two-cycle Elmore, as presented in the form of a splendid working model, driven by an electric motor, "looks good" to the expert and the layman alike. Certainly nothing could emphasize more strongly the absence of valves and other complications, while the answer to any other objections is found in the number of Elmore's that are running and making good.

The Oldsmobile four-cylinder car has joined the ranks of those to discard the tubular front axle for the more popular I-beam. With this, and at a slightly increased price, the stroke and bore have been both increased a quarter of an inch, raising the power from 28-30 to 35-40.

The unusual idea on the Corbin car is most strongly expressed in the double expanding brakes, a pair in each rear hub, one worked by pedal and the other by the emergency lever. Another feature that is unique is the use of Hess-Bright bearings on the crankshaft ends alone, the other three crankshaft bearings being of the plain type.

WHERE THE AIR-COOLED FRANKLINS REIGNED SUPREME.

THE PEERLESS WAS EFFECTIVELY DISPLAYED.

LOCOMOBILES MADE AN ATTRACTIVE SHOWING.

THE AMERICAN CARS OF 1907 IN GENERAL

AUTOCAR models for 1907 comprise a complete series from runabouts to limousine and landaulet. One of the most radical improvements is the three-point suspension of the power plant. Motor, flywheel, clutch, and transmission are inclosed in an aluminum housing, bolted together and supported as a unit at three points, two arms from the motor to the side members of the frame, and the third point under the transmission is seated on a stiff spring. This method of supporting the power plant does away with sub-frame construction, lessening the weight of the cars. Motor is now much more powerful, frame is of channel steel, and on Model XIV. the wheelbase has been increased to 112 inches. Road wheels have been increased to 34 inches, metal mud guards are employed, side entrance is wider, there is a light mahogany dash and a new design of radiator and hood with the radiator placed directly over the front axle, giving the car a very rakish appearance.

Apperson.—The entire attention of this concern is devoted to the construction of a four-cylinder, 50-horsepower model with independent cylinders 5 1-2 by 5 inches. Valves are on opposite sides. The engine is water-cooled, a tubular radiator being carried. Ignition is by high-tension magneto and accumulator. The clutch is of the constricting band type, selective change-speed gear is employed, giving four speeds and reverse, and final drive is obtained through side chains. Selling price is \$5,000.

Buick.—A 22-horsepower touring car and four types of 25-30-horsepower touring or runabout machines constitute the 1907 Buick designs. The 22-horsepower machine has two-cylinder opposed engine, 4 1-2 by 5 inches, plain bearings, valves placed in the head, water-cooling with tubular radiator and gear pump. The 25-30-horsepower model is a four-cylinder machine 4 1-4 by 4 1-2, cylinders cast in pairs, valves on one side, disk clutch and shaft drive. A special feature of the 25-horsepower machine is the selective type planetary transmission (Buick design).

Cadillac.—Nine models constitute the Cadillac line for 1907. Of these five are made by using different bodies on the 10-horsepower chassis, as follows: Model K runabout, \$800; Model M light touring car, \$950; Model M with folding tonneau, \$1,000; Model M coupé, \$1,200, and Model M light delivery wagon, \$950. The motor in the above models is the same as the Cadillac company has used in all its small cars and has single cylinder, 5 by 5, copper water jacketed. Pressed steel frame is used, wheelbase is 76 inches. Model H, a 30-horsepower car, will form the leader of the Cadillac line. An entirely new machine is Model G, a 20-horsepower four-cylinder automobile. In designing the new models all distinctive Cadillac features have been retained.

Although the three speed planetary gear is still retained on the heavier model for 1907, Model G has been fitted with a selective type of sliding change-speed gear, designed on modern lines. Both the main driving shaft and the countershaft run on roller bearings in steel bushings. This change-speed gear gives three speeds forward and reverse, control being by a single lever operating in the usual H-shaped quadrant, and when the direct drive is employed no gears are in mesh and the countershaft is idle.

Columbia.—Chief among the Electric Vehicle Company's models is a gasoline-electric automobile. The motor is of the standard four-cylinder vertical type employed on Columbia cars with the difference that the flywheel has been displaced by the generator in direct connection with the crankshaft of the motor and hardly occupying more space than the wheel which it displaces. Immediately behind the generator the motor is placed, though there is no mechanical connection between the two on any but the high speed, when the crankshaft of the motor and the propeller shaft terminating at the live rear axle become solidly coupled and both the dynamo and motor run dead. The low speeds, of which there are five forward and a reverse, are all provided by means of a small lever similar to the controller handle on street railway cars. No storage batteries are employed. The low speeds are used in starting, the motor being capable of a heavy overload, and when up to speed a clutch is employed to couple the motor and propeller shafts, the car running exactly as one equipped with the usual change-speed gear. Gasoline automobiles include a standard touring car and a limousine, both of 24-28 horsepower and a 40-45-horsepower machine.

Corbin.—A 24-horsepower air-cooled machine is the sole representative built by this company. The engine is of the vertical four-cylinder type, cast separately and air-cooled by a special system. Cylinder dimensions are 4 1-4 by 4 1-4. Valves are placed in the head, operated by rocker arms. The clutch is of the cone type, there is selective change-speed gear and shaft drive. Wheelbase is 108 inches and weight 2,200 pounds. \$2,500 is the list price of the machine, the seating accommodation of which is five persons.

Elmore is the steadfast exponent of the two-cycle principle, all its models at the Garden Show being of this type. They consist of a four-cylinder 30-35-horsepower, with a long wheelbase and luxurious body, selling for \$2,500; a three-cylinder 20-24-horsepower touring car listed at \$1,750, and a very racy three-cylinder runabout with turtle deck, giving ample space for spare tires, dress case or trunk. Owing to numerous inquiries received relating to the two-cycle principle, the Elmore company shows

a sectional engine run by electricity. Much attention has been paid to the refinement and perfection of small details, these minor changes being responsible for the great increase in power of the new engine over last year's models.

Franklin lines consist of ten models, using three different size motors, 12, 20 and 30-horsepower. Five distinct types are exhibited at the Garden Show: Type G, four-cylinder 12-horsepower light touring car, at \$1,850, with sliding-gear transmission, shaft drive and a speed of 35 miles per hour; type D, five-seated, 20-horsepower four-cylinder car, with sliding-gear transmission, three speeds, shaft drive, giving a speed of 45 miles per hour, price \$2,800; type H, seven-seated, six-cylinder 30-horsepower touring car, with sliding-gear transmission, shaft drive and giving a speed of 50 miles per hour price \$4,000; type G is an \$1,800 four-cylinder runabout of 12 horsepower, carrying two passengers and having sliding-gear transmission, three speeds and shaft drive; type J, a light commercial truck, listed at \$2,000, develops 12 horsepower, has sliding-gear transmission, three speeds and worm gear drive. No changes have been made in distinctive Franklin features, though improvements have been made in several places. Bodies are more spacious and planned to give greater convenience. The oiler has been removed from dash and placed at side of engine base where it is operated by direct gear. Larger wheels are used, giving greater road clearance, and all models are equipped with new self-finding gear-shifting device. The transmission universal joint block is of new design, the valve action has been improved, and a new style of connectionless intake pipe is used on all models.

Haynes.—The Haynes showing consists of a 50-horsepower limousine, a 30-horsepower landaulet, a 50-horsepower tonneau, a 30-horsepower touring car, and polished chassis of both the 50 and 30-horsepower models. One of the features of the exhibit was the Vanderbilt Cup racers, recently purchased by William C. Thorn, of Chicago. Haynes models have all four cylinders, cast in pairs for the 30-horsepower machine, but independent on the 50-horsepower model. Valves are on opposite sides. Water-cooling is by honeycomb radiator and rotary pump. Ignition is by high-tension magneto and sparking plugs. Drive is by propeller shaft to rear live axle. Roller bearings are employed throughout.

Hewitt.—Two different chassis only of the Hewitt automobile are constructed for pleasure use. One, a 10-horsepower single-cylinder runabout or town car; the other, an eight-cylinder developing 50-60 horsepower. The single-cylinder machine is listed at \$1,000 as a runabout and has a seating capacity for four. Its mechanical features are disk clutch, planetary change-speed gear and single chain drive. Wheelbase is 72 inches. The 50-60 model has two rows of cylinders forming a V, two pairs on each side. Disk clutch is employed, planetary speed-change gear and shaft drive. Valves are all on one side; water-cooling is by cellular radiator and centrifugal pump.

Knox.—A patented system of air-cooling is the distinctive feature of all Knox cars, the model G, of 35-40 horsepower, being the leader for 1907. A complete line of pleasure vehicles is constructed, among them being a stanhope, a distinctly new type of high-powered runabout of light weight, and a new model, H, of 25-30 horsepower. A distinct novelty is an automobile fire wagon mounted on a standard 40-horsepower chassis, carrying chemical fire extinguishers and having accommodations for a number of firemen. Two new trucks with a load capacity of 5,000 and 6,000 pounds respectively, are also a feature of the Knox line for the coming year.

Lozier models consist of a regular 40-horsepower type F seven-passenger touring car, a 40-horsepower runabout finished in royal purple and upholstered in French gray leather, a 40-horsepower limousine and a 60-horsepower touring car. Apart from the chain cases there is nothing of a startling nature, all well-tried features of last year being retained. They include pistons lathe-turned inside and out; crankshaft machined from solid slab of 30-point carbon steel; camshafts made from solid bar; double ignition system with independent plugs for each system, Simms-Bosch magneto supplying current for one with a Witherbee storage battery for reserve. Water-cooling is by two fans, one back of radiator, the other formed by flywheel blades; sliding-gear transmission, four forward speeds, selective type; safety dog and ratchet back-stop device on jackshaft; Hess-Bright D. W. F. ball bearings throughout; multiple disk clutch in oil-tight case; a clutch brake stops motion of gears and prevents clashing. Water-cooling is fitted for brakes, and emergency brake has lever pulling towards operator. A continuous aluminum pan entirely protects motor. Drive is by side chains.

Locomobile.—Two standard models of 20 and 35 horsepower, each of which is fitted with either open or closed body, are exhibited. A distinctive feature of the showing is the number of drop forgings made for the 1907 product. The Locomobile Company has always made its own forgings, but the number of pieces for 1907 is greater than ever before owing to the fact that the facilities of the forge shop at Bridgeport have been increased materially. They range from tiny forgings the size of a door key and weighing an ounce or so to massive forgings for axles, shafts and other large components of the car. The 90-horsepower racer which Tracy drove in the Vanderbilt Cup contest was on view and attracted considerable attention.

Matheson.—Two chassis are produced by the Matheson Motor Car Company. One is of 35 horsepower and the other of 50 horsepower, these two replacing the 40 and 60 models of last year. Four different styles of body may be fitted to each chassis—runabout, regular touring body, landaulet and limousine. The Matheson carries a four-cylinder vertical motor, has sliding-gear transmission and double chain drive. A distinctive feature is the ignition system of make-and-break type with a low-tension alter-

ALL AUTOCAR TYPES FOR 1907 WERE SHOWN.

"BIG SIX" AND "LITTLE SIX" THE ATTRACTIONS.

AT THIS STAND THE TWO-CYCLE WAS KING.

SIMPLEX MODELS OF SMITH & MABLEY.

nating magneto of the Simms-Bosch make as a source of current. Extensive improvements have been made in the carbureter, which is different from that of last year, being new in many respects as the result of close study given this essential. The cylinders are cast individually with integral water jackets and mechanically-actuated valves by a special form of superimposed type of camshaft. A useful device fitted to the machine is a hill pawl by which the operator can stop the car while ascending a grade and hold it without using the brakes.

Northern.—Two distinct models of Northern automobiles are manufactured for 1907. The smaller is a 20-horsepower double-opposed motor carried transversely on the frame, cylinder dimensions being 5 1-2 by 5 1-4. The engine is water-cooled and carries a tubular radiator and rotary eccentric pump. Expanding ring clutch is employed, change-speed gear is of the planetary type, and shaft drive is used. With a touring body this automobile seats five and is listed at \$1,700. In the 50-horsepower type the four vertical cylinders, 5 by 5 1-2 inches, are of one casting, with valves placed in the head, using rocker arms. The engine is water-cooled and carries a tubular radiator; clutch is of the compressed-air type, three speeds and reverse are obtained through sliding gears and shaft drive is employed. Seven persons can be carried in the 50-horsepower model, the selling price of which is \$3,500.

Olds.—The new Oldsmobile model has a four-cylinder vertical water-cooled motor, developing from 35 to 40 horsepower, of the same design that has proved so successful during the past year. On this chassis three different styles of car will be built, a palace touring car selling for \$2,750, a flying roadster at the same figure, and a limousine listed at \$3,800. Accessibility has been sought throughout, and by removing the hood the entire motor may be examined. Mechanical features are interchangeable valves, aluminum crankcase and improved piping arrangements. Transmission control and clutch remain practically the same as last year, with a few minor changes. A larger and better equipment has been added, consisting of full set of tools, two acetylene head lamps and well designed luggage carrier. The limousine has received special attention in upholstery and finish; every detail has been well thought out down to speaking tube, electric lights, toilet set, and other small but essential conveniences.

Orient and Waltham Orient.—The models of these lines consist of three types of single-cylinder machines of 4 horsepower, with friction clutch, double chain drive, air-cooled and high-tension ignition; a four-cylinder runabout of 16-20 horsepower, selling at \$1,750, and a four-cylinder touring car of 20 horsepower, listed at \$2,100, with cone clutch, sliding change-speed gear, shaft drive, wheelbase 96 inches, weight, 1,850 pounds. All Orient models are air-cooled, cylinders, of course, being independent and valves are all on one side.

Packard.—Only one model of the Packard machine is manufactured. It is a four-cylinder 30-horsepower automobile with 5 by 5 1-2 cylinders cast in pairs, valves on opposite sides, water-cooling with tubular radiator and gear pump. The clutch is of the internal expanding type, sliding change-speed gear is employed together with shaft drive. In reality the single model divides itself into two, one being a runabout with 108 inches wheelbase, the other a touring car of 122 inches wheelbase; a handsomely equipped limousine is also shown in the Garden. Mechanical features are identical and the list price, \$4,200, is the same for the two, while the limousine sells at \$5,500.

Peerless.—Two 45-horsepower models and one 30-horsepower machine are built by the Peerless company. In each type the cylinders are cast in pairs with valves on opposite sides, water circulation being provided by a tubular radiator and a gear-driven pump. Cylinder dimensions of the 45-horsepower chassis are 5 1-4 by 5 3-4; for the 30-horsepower they are 4 5-8 by 5 1-2. Change-speed gear is of selective type; internal expanding band clutch and shaft drive are employed. Wheelbase is 109 inches on the lower power and 114 inches on the larger model. This firm is the only one to exhibit a limousine with inside steering.

Pierce Great Arrow.—A 65-horsepower six-cylinder car is the leading feature of the Pierce line for the coming season. Other types are a 45-horsepower runabout, selling at \$5,000, and a 28-32 "Suburban" model. The six-cylinder car of Glidden Tour fame has independent cylinders 5 by 5 1-2 inches, valves on opposite sides, disk clutch, sliding-gear transmission and shaft drive. Wheelbase is 122 inches and weight 3,500 pounds. Ignition is by high-tension Simms-Bosch magneto with accumulator in reserve. A cellular radiator is employed, fed by a centrifugal pump.

Pope-Toledo, Pope-Hartford, Pope-Tribune.—There is a comprehensive list of models from the Pope factories, comprising Pope-Waverley electrics, Pope-Toledo, Pope-Hartford and Pope-Tribune gasoline automobiles. Pope-Toledo models include a 50-horsepower touring machine, at \$4,250; 50-horsepower runabout, at \$4,250; also limousine, demi-limousine and landaulet. Pope-Hartford lines are 25-30-horsepower touring car, at \$2,750; 25-30-horsepower runabout at the same price, in addition to limousine and landaulet models. A Pope-Tribune runabout of 16-20 horsepower is listed at \$1,750. An entirely new model is the 50-horsepower four-cylinder Pope-Toledo with multiple disk clutch, selective type of change-speed gear and double chain drive. Wheelbase is 115 inches and weight 2,900 pounds.

Royal Motor Car Company.—Only one type of Royal Tourist automobile is constructed. Rated at 45-horsepower, it carries a four-cylinder motor with 5 1-8 by 5 1-2 cylinders cast in pairs; water-cooled by cellular radiator and rotary pump. Valves are on opposite sides. Change-speed gear is of the sliding type, cone clutch is employed, and final drive is by shaft. Wheelbase is 114 inches. Selling price is \$4,000. On this chassis several

types of bodies are furnished, ranging from a simple runabout to an elaborately finished and equipped limousine.

Simplex.—Two Simplex models are presented for 1907. One is rated at 30-35 horsepower, the other at 50 horsepower. In each case the engine is of the four-cylinder type, cylinders 4 1-2 by 5 1-2 for the 30-35; 5 7-8 by 5 7-8 for the 50 horsepower, cast in pairs. Water-cooling is employed, using a honeycomb radiator and centrifugal pump. Change-speed gear is of the selective type, giving four speeds forward and reverse, cone clutch is used, and drive is by side chains. Bronze and babbitt bearings are used throughout. The Simplex runabout is listed at \$5,760. Price of the 30-35-horsepower model varies according to body, chassis alone selling at \$4,950.

Stearns.—One type of chassis only is made by the Stearns company. Its rating is given as 30-60 horsepower; this is explained by the fact that a special system of carburetion has been adopted. It consists of a small and a large carburetor fed from a common float chamber. On the small one the motor develops 30-horsepower, the larger not coming into service until the small one is fully open. The four cylinders are cast in pairs, their dimensions being 5 3-8 by 5 7-8. D. W. F. ball bearings are used throughout and valves are all on one side. The engine is water-cooled, a tubular radiator and rotary pump being employed. The clutch is internal expanding, the selective change-speed gear gives four speeds and reverse, and final drive is by double chains.

Stevens-Duryea.—This line includes one four-cylinder, developing 20 horsepower, and two six-cylinders, one of them of 35 horsepower and the other of 50 horsepower. On all three models the cylinders are cast separately and are water-cooled through cellular radiator and centrifugal pump. Bearings are plain, valves are on one side and high-tension ignition is employed. Both four and six-cylinder types have disk clutch, sliding change-speed gear and shaft drive. The Stevens-Duryea company is a pioneer in six-cylinder construction. The success which has attended their efforts is shown by the fact that this year they produce two six-cylinder models. Wheelbase of the "big six" is 122 inches, rear springs are 54 inches in length, and front springs 54 inches. With a touring body there is seating accommodation for three persons on rear seat, two on the extra Pullman seats, and two in front. Including a full equipment, this machine is \$6,000.

Studebaker.—The chief gasoline car manufactured by this company is a 30-35-horsepower chassis, the features of which are four cylinders measuring 4 1-8 by 5 1-4 inches, cast in pairs, water-cooling, cellular radiator, low tension magneto, cone clutch, sliding change-speed gear, giving three speeds and reverse, and shaft drive. Wheelbase is 104 inches.

Thomas Flyer.—In general outward appearance the Thomas 60 horsepower flyer for 1907 does not differ materially, with the exception of the changed outline of the radiator and bonnet, from

its predecessor of the year previous, though there have been many changes in refinement, simplification and last but by no means, least lightening of the gross weight of the car. The four-cylinder motor rated at 60 horsepower is one of the points on which weight has been saved, yet it has been made stronger and better able to perform the service required of it, due to improved methods of construction. The cylinders are cast separately with integral water-jackets; valves are all mechanically operated, oppositely disposed and are interchangeable. Two separate and distinct ignition systems are fitted, each being of the high tension type and having an independent set of plugs. The current for one is supplied by a Simms-Bosch high tension magneto, while a set of accumulators working through an Atwater-Kent spark generator comprises the other system.

Thomas "Forty."—A four-cylinder engine with cylinders of 4 3-4 by 5 inches, cast in pairs, valves all on one side, water-cooling through tubular radiator and centrifugal pump, cone clutch, selective type of change-speed gear, and shaft drive are the outstanding features of the Thomas "Forty." An interesting departure from standard practise is embodied in the valve operating mechanism rendering the setting of the valves readily adjustable. The suspension is of the semi-elliptic type both front and rear, the latter measuring 52 by 2 1-4 inches, and the former 36 by 2 inches. A pressed steel frame of the usual channel section is employed, with a subframe dropped four inches for the support of the motor and transmission. Two sets of brakes are fitted.

Walter.—This line consists of a 40-horsepower car with cylinders 5 by 5 1-2 and a 50-horsepower 5 1-2 by 6, each with four cylinders cast in pairs. Valves in each case are placed in the head and on the side. Ignition is by high-tension magneto and accumulators in both cases. Each type may be had with either disk or cone clutch, change-speed gear is of the double sliding type, and shaft drive is employed. Wheelbase in each type is 124 inches. The engine is water-cooled, the radiator being of the honeycomb type.

Winton.—Two distinct models are put forth by the Winton Company for 1907, a 30-horsepower car, known as Type XIV, and an entirely new machine of 40 horse power, known as Model M. The chief feature in which the latter differs from its predecessors is in having off-set cylinders, change-speed gear of the selective sliding-pinion type, and a channel section pressed-steel frame in place of the armored wood frame employed on the lighter car last year. The motor of the new car has 5 by 5 cylinders cast in pairs, with water jackets completely surrounding each cylinder. Valves are all on one side. A multiple disk clutch is employed, housed in the same aluminum casing as the change-speed gear. Four speeds and reverse are obtained by the selective type of gear-change mechanism. Final drive is by propeller shaft and rear live axle.

MATHESONS AND STEARNS WERE ELEVATED.

THE GARDEN HOME OF THE CADILLACS.

AT THE LEFT OF THE ENTRANCE TO THE BIG AMPHITHEATER THE EXHIBIT OF FIATS WAS IMPRESSIVE AND COMPLETE.

THE FOREIGNERS OF THE GARDEN SHOW

WITH twelve of the most important European firms exposing at Madison Square Garden, and including such constructors as Renault, Panhard, C. G. V., Bayard-Clément, Darracq, Hotchkiss, Dietrich and Rochet-Schneider from France; Fiat and Isotta Fraschini from Italy, and Daimler from England, the promoters may justly claim to have united the world's best automobile construction outside the United States. In every case 1907 models are shown, and although the booths do not contain an example of every model produced, in all cases the factories' best is on view. As in the case of Bayard-Clément and Darracq, small runabout models are not always handled in America owing to the high duty. European constructors are too much impressed with the importance of the American market not to make a strong effort, despite the difficulty they have in being ready for the Paris Salon, to ship over their new products for exhibition at our national show.

Renault.—Six distinct models are made by the Renault firm for 1907. The 35-45, 20-30, 14-20 and 10-14 have four vertical cylinders; a 10-14 and an 8-9-horsepower model have each two vertical cylinders. In general construction the 1907 models are very similar to those of last year, main features being cylinders cast in pairs, with mechanical valves all on one side, no governor, ignition by Simms-Bosch magneto and sparking plugs, automatic carbureter, thermo-siphon water cooling with tubular radiator forming dashboard, leather-faced cone clutch and transmission by cardan shaft to rear axle. The change-speed gear gives four speeds forward and reverse with a "straight through" lever. A new feature is the adoption of three-quarter elliptic rear springs in place of transverse rear spring previously employed. The 10-14-horsepower two-cylinder machine, extensively employed in European cities for cab work, differs from the larger models in only having three forward speeds. Transverse rear spring is retained on this model. The 8-9-horsepower is but a reduction of the larger type. A self-starter can be supplied with the larger Renault models.

C. G. V.—These cars for 1907 are of 20, 30, 50 and 75 horsepower. In addition a 14-horsepower machine has been designed specially for town use embodying many new features. All models have four separate cylinders with mechanically-operated valves on opposite sides. Ignition is by magneto and sparking plugs, transmission through countershaft and side chains to rear wheels, direct drive on the high gear, and straight-through type of lever.

Water circulation is obtained by gear-driven pumps, and lubrication is of force-feed type. Ball bearings are employed throughout. A new feature is the use of chain cases and a special device for regulating tension of chains. The 14-horsepower town model has drop frame, longitudinal C and transverse rear spring, transmission by cardan shaft to rear axle, and driver's seat placed at the left instead of the right-hand side. Levers are consequently in the center.

English Daimler.—The cylinders on this machine are cast in pairs, with all valve chambers on left-hand side and one camshaft accordingly, but a light shaft is fitted on the other side of engine for driving pump and magneto. Engine and gear box are carried by brackets direct on to frame, three-point suspension being employed. Carbureter is on usual lines, but modified to give better proportion of mixture at all speeds. High-tension accumulator-fed synchronized ignition is fitted. The low-tension contact maker and high-tension distributor are set on the top of a vertical shaft at left-hand front of engine and driven by bevel gearing from forward end of camshaft. Water is delivered from the circulating pump to the end of each valve chamber, passes across the bases of the valve chambers, flows upwards around each valve and returns to radiator over crown of combustion chambers. Standard clutch is retained, but is now carried on extension of crankshaft.

Darracq.—These models are very complete. Beginning with a six-cylinder machine, 100 mm. bore by 120 mm. stroke, they descend down in easy stages to small runabout of moderate power. The six, an entirely new machine, is the most interesting of the lot. Its distinctive features are transmission by cardan shaft with double joint between the gear box and motor to rear live axle. Cylinders are cast in pairs, with valves all on one side; ignition by high-tension magneto. Of the light cars there are a two-cylinder 10-12-horsepower and a four-cylinder 16-18-horsepower model, both made with either long or short chassis for tonneau or side-entrance body. There are two models of four-cylinder touring cars, each of 20-28 horsepower, differing only in their change-speed gear. A self-starter is fitted to the larger machines at an extra cost. Instead of change-speed lever being placed below steering wheel, it is now on the side of the car, according to general custom.

Fiat.—A six-cylinder 50-horsepower chassis with self-starting apparatus, a 35-horsepower four-cylinder runabout, and

a 15-horsepower town chassis are the chief Fiat productions for 1907. Cylinders are cast in pairs, valves are on opposite sides, ignition by low-tension magneto, water circulation by centrifugal pump and honeycomb radiator. Ball bearings are used throughout, there are four speeds forward and reverse, with gate type of change-speed gear. The Fiat novelty for 1907 is the 15-horsepower chassis specially designed for town use. It has a special drop frame, allowing of a very low side entrance, and transmission by cardan shaft to rear axle. Another Fiat feature is a two-seated runabout specially constructed for American roads, having special luggage-carrying facilities and a seat for chauffeur on the footboard.

Bayard-Clément.—This firm has adhered closely to last year's design in constructing the 1907 models. Ignition is now by magneto and sparking plugs for all machines, but all other Bayard features have given so much satisfaction that it has not been thought necessary to make changes. A new two-cylinder two-seated runabout has been created to meet a popular demand as well as a moderate-priced four-cylinder runabout at a low price. The low and moderate power machines have transmission by cardan shaft, the 24-30-horsepower, the 35-45 and 50-60 all have drive through countershaft and side chains to rear wheels. No six-cylinder models are constructed. The fours have separately cast cylinders with valves on opposite sides, all interchangeable. A metallic disk clutch is employed and the large models have ball bearings throughout.

Isotta-Fraschini.—The principal models of this Italian firm are a 35-horsepower four-cylinder runabout and a 50-65 six-cylinder machine. In both cases cylinders are cast in pairs with valves on opposite sides. Double chain drive is employed, there are four forward speeds and reverse, with selective type of change-speed gear and disk clutch. A new feature of the Isotta Fraschini models is a self-starter consisting of a gear-driven pump on the countershaft, compressing air into a metal tank placed in any convenient position on the chassis. Inlet piping connects up the tank to the motor, and by the pressing down of a lever the compressed air is admitted to those cylinders under compression.

Hotchkiss.—This concern devotes its attention chiefly to the new six-cylinder car, with three groups of cylinders placed as close together as possible to save space. Hotchkiss was a pioneer in the use of ball bearings, and has used them throughout in the new six. Valves are placed on opposite sides, camshafts are cut out of the solid and case-hardened. Timing gears are inclosed in oil-tight case at the front of motor and are metal against fibre. Ignition is by high-tension gear-driven Eiseman swinging magneto on the exhaust side. The carbureter is the new Mann type, warmed with hot air from the exhaust. Last year's honeycomb radiator and gear-driven pump are retained. Only slight changes have been made in the leather-faced cone clutch mounted on an extension of the crankshaft. Transmis-

sion is by cardan shaft to live axle, and brakes are double-acting type on shaft behind gear box and on steel drums on rear wheels. Two four-cylinder models are also constructed.

Panhard.—These models are 18, 24, 35 and 50 horsepower, all with four cylinders cast separately. The crankshaft has five bearings and lower half of crankcase can be taken off without disturbing the shaft. Valves are placed on opposite sides, water circulation is by gear-driven pump turning at the same speed as the motor, and a honeycomb radiator is employed. Ignition is by high-tension magneto and sparking plugs, accumulators also being carried. The magneto is mounted on the same shaft as the water circulating pump. A special metallic clutch is employed and transmission is by countershaft and side chains. There are four speeds forward and reverse with lever of the straight-through type. Brakes act on the differential and on the interior of drums on rear wheels.

Rochet-Schneider.—These models are four in number, rated at 16-20, 30-35, 40-45 and 70 horsepower. The first three have four cylinders cast in pairs, the 70-horsepower having six cylinders, also in pairs. Transmission in every case is by countershaft and side chains to rear wheels; ignition is by low-tension magneto, gasoline has pressure feed, water circulation by rotary pump and tubular radiator. There are four speeds and reverse on each model, with selective type of change-speed gear.

De Dietrich.—These types are 16, 24, 40 and 60 horsepower, all with four cylinders cast in pairs, but with a common water chamber for the whole group. Low-tension Simms-Bosch magneto is employed with sparking mechanism on side of cylinders. Water circulation is by gear-driven pump and gilled tube radiator. Gasoline tank is under pressure. Transmission is through countershaft and side chains, with "gate" type of change-speed lever.

Rolls-Royce.—Although enjoying a good reputation in England, where it won the important Tourist Trophy last year, the Rolls-Royce machine is practically unknown in America. Standard models are a 20-horsepower four-cylinder, a 30-horsepower six-cylinder, and a 40-50-horsepower six cylinder. The last named is an entirely new car having cylinders cast in sets of three with all the valves on one side, the whole being set upon an aluminum crank chamber of ample dimensions. The Rolls-Royce carbureter is accessibly placed on right-hand side of engine, the induction pipe leading away between the two sets of cylinders, joined up to the distributor pipe at the center. Exhaust pipes have rather a unique arrangement, there being a small expansion chamber to each set of cylinders leading away to the muffler below frame. Double ignition is employed, the coil and two-way switch being only parts carried on the dashboard. Final drive to the rear road wheels is through propeller shaft and bevel gearing. The whole of the mechanism is set upon a double cambered pressed steel frame mounted upon substantial springs, giving a very substantial look to the car as a whole.

DARRACQ EXHIBIT, WHERE VANDERBILT CUP WAS SHOWN.

BAYARD-CLEMENTS AS PRESENTED BY SIDNEY BOWMAN.

1907 MODELS OF THE LEADING MAKERS

PACKARD LANDAULET, 30-H.P., 4 CYLINDERS, PRICE \$5,500.
Packard Motor Car Co., Detroit, Mich.

PIERCE GREAT ARROW, 66-H.P., 6 CYLINDERS, PRICE \$6,500.
George N. Pierce Co., Buffalo, N. Y.

LOCOMOBILE MODEL H, 35-H.P., 4 CYLINDERS, PRICE \$4,500.
Locomobile Company of America, Bridgeport, Conn.

PEERLESS MODEL 16 LIMOUSINE, 45-H.P., 4 CYLINDERS, PRICE \$5,000.
Peerless Motor Car Co., Cleveland, O.

THOMAS FLYER LIMOUSINE, 60-H.P., 4 CYLINDERS, PRICE \$5,200.
E. R. Thomas Motor Co., Buffalo, N. Y.

FRANKLIN MODEL H, 30-H.P., 6 CYLINDERS, PRICE \$4,000.
H. H. Franklin Mfg. Co., Syracuse, N. Y.

ROYAL MODEL A LIMOUSINE, 45-H.P., 4 CYLINDERS, PRICE \$5,000.
Royal Motor Car Co., Cleveland, O.

COLUMBIA MARK XLIX, 40 to 45-H.P., 4 CYLINDERS, PRICE \$4,500.
Electric Vehicle Co., Hartford, Conn.

STEVENS-DURYEA "BIG 6," 50-H.P., 6 CYLINDERS, PRICE \$6,000.
Stevens Arms & Tool Co., Chicopee Falls, Mass.

LOZIER LIMOUSINE, 40-H.P., 4 CYLINDERS, PRICE \$6,000.
Lozier Motor Co., New York City.

POPE-TOLEDO MODEL XV TOURING CAR, 50-H.P., 4 CYLINDERS, PRICE \$4,250.
Pope Motor Car Co., Toledo, O.

WALTER LIMOUSINE, 40-H.P., 4 CYLINDERS, PRICE \$6,000.
Walter Automobile Co., Trenton, N. J.

KNOX MODEL G LIMOUSINE, 35 TO 40-H.P., 4 CYLINDERS, PRICE \$5,000.
Knox Automobile Co., Springfield, Mass.

HEWITT TOURING CAR, 50 TO 60-H.P., 8 CYLINDERS, PRICE \$5,500.
Hewitt Motor Co., New York City.

OLDSMOBILE LIMOUSINE, 40-H.P., 4 CYLINDERS, PRICE \$3,800.
Olds Motor Works, Lansing, Mich.

POPE-HARTFORD MODEL L, 25 TO 30-H.P., 4 CYLINDERS, PRICE \$2,750.
Pope Manufacturing Co., Hartford, Conn.

STEARNS TOURING CAR, 30 TO 60-H.P., 4 CYLINDERS, PRICE \$4,500.
F. B. Stearns Co., Cleveland, O.

MATHESON TOURING CAR, 50-H.P., 4 CYLINDERS, PRICE \$5,500.
Matheson Motor Car Co., Wilkesbarre, Pa.

HAYNES MODEL T LIMOUSINE, 50-H.P., 4 CYLINDERS, PRICE \$4,500.
Haynes Automobile Co., Kokomo, Ind.

NORTHERN MODEL C LIMOUSINE, 20-H.P., 2 CYLINDERS, PRICE \$2,800.
Northern Motor Car Co., Detroit, Mich.

SIMPLEX LIMOUSINE, 30 TO 35-H.P., 4 CYLINDERS, PRICE \$6,500.
Smith & Mabley, Inc., New York City.

CORBIN MODEL H LIMOUSINE, 24-H.P., 4 CYLINDERS, PRICE \$3,500.
Corbin Motor Vehicle Corp., New Britain, Conn.

WALTHAM ORIENT TOURING CAR, 20-H.P., 4 CYLINDERS, PRICE \$1,750.
Waltham Manufacturing Co., Waltham, Mass.

FRANKLIN MODEL D, 20-H.P., 4 CYLINDERS, PRICE \$2,800.
H. H. Franklin Mfg. Co., Syracuse, N. Y.

CADILLAC MODEL G, 20-H.P., 4 CYLINDERS, PRICE \$2,000.
Cadillac Motor Car Co., Detroit, Mich.

NORTHERN MODEL L, 50-H.P., 4 CYLINDERS, PRICE \$3,500.
Northern Motor Car Co., Detroit, Mich.

COLUMBUS ELECTRIC INSIDE-DRIVEN COUPE, PRICE \$1,900.
Columbus Buggy Co., Columbus, O.

Lozier Motor Co., New York City.

PIERCE GREAT ARROW TOURING CAR, 40 TO 45-H.P., 4 CYLINDERS, PRICE \$5,000.
Geo. N. Pierce Co., Buffalo, N. Y.

BAKER SHAFT-DRIVEN ELECTRIC ROADSTER A LA RACEABOUT, WITH BATTERY UNDER THE BONNET.

THE FIELD OF THE HORSELESS ELECTRICS

LUXURY of appointments, combined with mechanical simplicity and ease of control, are the chief characteristics of the electric vehicle, and they are exemplified in no small degree by the cars now on view in this section of the show. It goes without saying that they represent the product of the best known makers in their line in this country, if not in the world, for the American-made electric vehicle has gained prestige abroad as well as on this side of the Atlantic. The motive power really forms so small and apparently so insignificant a part of the up-to-date electric vehicle that it is scarcely to be wondered at that the ingenuity and lavish disregard of expense displayed in the fitting of the interiors of this type of car should constitute their chief attraction. In all that pertains to the comfort of the occupants, as well as the manner in which both the fitting and finish are executed, it is evident that the builder of the electric vehicle found that the carriage maker had stopped far short of the attainable and had no difficulty in greatly surpassing him—a respect in which he also anticipated the body builder of the gasoline car, although the latter has since come abreast of him, there being little to choose between the appointments of the up-to-date limousine or other inclosed type of body, and the smart electric vehicle.

Where the purely mechanical side is concerned, no one realizes better than the electric vehicle builder himself that progress must necessarily be slow. But at the same time no one realizes the extent of the progress that has been made in storage battery manufacture within the past few years. It is difficult to talk of improvement in this respect to the layman without exaggerating things, and there has been so much misleading information given to the public on the subject in that time that makers have since refrained from calling the public to witness their achievements, except where the latter have been of a radical or revolutionary nature. Compound wound motors of low powers, but capable of standing excessive overloads for long periods, are still characteristic of the power equipment; but there has been more or less change in the manner of applying the power, which is to be noted in the increasing popularity of the single-

motor, shaft-driven type of car. Barring these, and with a few well-known exceptions, most of the cars are chain driven, the former employing gears, which are, however, no longer in general use for this purpose on the ordinary type of electric pleasure vehicle. Another thing noticeable is the extent to which the evolution of the up-to-date gasoline car has aided the builder of the electric, the latter having been able to adopt many of the innovations introduced primarily as constructional features of the gasoline car.

Baker Motor Vehicle Co.—Baker electrics are probably typical of this, in that the *pièce de résistance* of the Baker exhibit is an electric roadster, which at first glance might well be taken for a gasoline car, so closely does its appearance approximate to the latter. It is planned on the lines of the modern high-powered gasoline runabout, with two bucket seats about the center of the wheelbase and the usual dickey seat behind, in this case to the extreme rear and behind the back axle. Steering is by the usual inclined wheel, the steering pillar also carrying the controller lever, the control being placed at the left hand of the car. Forward of this is what appears to be the regulation type of bonnet, sheltering the battery, though it would hardly be suspected of having been placed there for that purpose except upon investigation. Hung quite low and approximately beneath the center of the car in order to bring the center of gravity down is the power plant in the shape of a single electric motor direct connected to a propeller shaft driving the rear wheels through the medium of a bevel gear and live axle. In addition to this roadster, which represents an unusual attraction in the electric field, the Baker interests are also displaying a standard runabout, listing at \$1,800; a brougham of new design and very attractive lines at \$4,000, the option of a landaulet body also being given on the same chassis at the same figure. There is also a stanhope at \$1,600 and a victoria at \$3,000. The batteries in the smaller and lighter vehicles consist of 24 cells and 40 cells in the larger. All are equipped with pneumatic tires, varying in diameter and wheel size in accordance with the weight, the mileage ranging from 40 to 80 miles on a single charge.

Pope Manufacturing Company.—Pope-Waverley electric vehicles are shown in such a wide range of types that it is possible to find in this exhibit, which is one of the largest and most representative of its kind, a car adapted to any purpose within the range of the electric vehicle. The leading car of the exhibit is a dainty stanhope of special design, listing at \$2,000. It carries a battery of 30 cells. The standard type of stanhope is listed at \$1,400 and has the same battery, while a victoria-phaeton at \$1,600 comes between these two. The last named also carries 30 cells of battery, the weight being equalized by placing 10 cells forward and the remainder in a rear compartment. Its body is a special design, on which a patent has been applied for, one of the features being the dropped sill or floor support, materially lessening the distance between the floor of the car and the ground, beside which the seat is broad and low. With the exception of the station wagon, which constitutes an attractive feature of the exhibit, all the types shown are equipped with 30 cells of Exide battery, this having 41, different types of varying capacity being employed in accordance with the needs of the car. As an option, the National cells are also offered. Both the two models of stanhope as well as the victoria-phaeton are equipped with a single motor of high overload capacity, driving the rear wheels through the medium of the special "herring-bone" type of gear, which has always been a distinctive feature of the Pope electric vehicles.

Cantono Electric Tractor Company.—Cantono fore carriages constitute a line which represents quite a departure from the regulation standard type of electric vehicle. As their name indicates, the motive power is concentrated on the forward truck or axle carrying the front wheels, which accordingly act as the drivers, contrary to the usual custom of driving the rear wheels, though in this case the forward wheels also serve for the steering in addition. Two types are shown, a fore-brougham with extension straight front and a fore-landaulet, both of which list at \$3,500. Motors, batteries, controllers and all connections are self-contained on the front part of the car, the wheels of which are accordingly equipped with heavier tires owing to the extra weight and duty imposed upon them. They are equipped with 5-horsepower motors, have a 90 and 96-inch wheelbase, respectively, weigh 3,000 pounds in both instances, and are equipped with 44 cells of battery, giving an effective radius of 40 miles.

Babcock Electric Carriage Company.—Babcock is a name that has stood for electric vehicles in this country almost as long as they have been a feature of the automobile world, so that it is only to be expected that the vehicles turned out under this mark should be representative of the latest achievements in this line, both where electrical efficiency

and refinement of detail in equipment are concerned. Prominent among the models specialized by the makers of this line are to be found a stanhope at \$1,650, a victoria at \$1,600 and a roadster of special design at \$1,400. The power plant consists of a 2 1-2-horsepower, specially wound, electric motor capable of standing excessive overloads for a considerable length of time, 24 cells of battery being employed in every instance, with the exception of the stanhope, which carries 40 cells. This keeps the weight down to an extremely low limit, the roadster tipping the scales at but 1,500 pounds, the victoria being only 50 pounds heavier, while the stanhope weighs 1,900 pounds. Such a ratio of power to weight spells efficiency, which is exemplified in the 100 mile radius of the specially designed roadster.

Electric Vehicle Company's models in all types have long been looked upon as standard designs in this field, and the exhibit made by the company reflects the high position it has occupied in the building of this type of vehicle ever since its inception. Its lines of cars of the heavier types is the most complete shown, including as it does a victoria, brougham and landaulet, beside which there is a private hansom—the only one staged. The vehicles all carry 44 cells of the Exide battery, of which this company is the maker, and are all listed at the same price, namely, \$4,000. It goes without saying that in refinement of mechanical detail, which in the case of the electric vehicle is spelled in terms of mileage per charge more than anything else, as well as in luxury of appointments for the convenience and comfort of the passengers, these cars have been brought to a point where it is difficult for the carriage builder to carry his art any further. The line is completed by a light victoria-phaeton of special design, equipped with 24 cells of battery of a smaller capacity owing to the great difference in weight between this and such types as the brougham. It runs on pneumatic tires, as do all the other models as well, and is listed at \$1,500.

Columbus Buggy Company.—Columbus electric vehicles are illustrative of what a really short step it is from the building of the horse-driven type of carriage to the electric, though on the other hand they likewise show in a striking manner how much the carriage maker's art has been advanced by the advent of the electric. The long experience in the manufacture of carriages enjoyed by these builders before entering the field of electric vehicle building proved the best possible kind of stepping stone for the latter; for, after all, the electric is the closest possible approach to the "horseless" carriage which the maker of gasoline cars found did not represent either a mechanical or aesthetic ideal upon which to build with the form of motive power at his command. Among the cars shown by this firm are a stanhope and coupé, listing at \$1,600 and \$1,900, respectively, and two surreys at \$2,500 and \$3,000. Twenty-four cells of battery are used in every instance, the effective radius being 40-75 miles in the case of the lighter vehicles, and 50-60 miles for the surreys.

Studebaker Automobile Company.—Studebaker is also a name that has long been identified with the building of electric vehicles for pleasure use, the amount of attention of which this branch of the many business interests of this firm is the recipient being well indicated by the great range of electric vehicles shown by it. In fact, the Studebaker exhibit, insofar as the number of styles shown is concerned, may well be put down as the most complete of its kind. In support of this, it may be mentioned that no less than six distinctive types of car are shown, ranging from a small runabout to a heavy surrey. Both this and the standard type of stanhope put out by this firm have a 67-inch wheelbase, with a weight of 1,650 and 1,565 pounds, respectively. Then there is a special stanhope on a 74-inch wheelbase; a coupé on a 68-inch wheelbase, and a special surrey. The runabout lists at \$1,135, the stanhope at \$1,275, victoria-phaeton at \$1,775, coupé at \$2,225, special stanhope at \$1,675, and the surrey at \$2,985.

HOW THE MONSTERS LOOKED WHEN AT REST.

AISLES ARE WIDE AND COMMODIOUS, BUT THEY ARE CONGESTED WITH PEOPLE AFTERNOON AND EVENING.

THE COMMERCIAL VEHICLES OF THE SHOW

By HOWARD GREENE.

DOWN in the basement of the Garden, below the main floor, are the commercial vehicles—those quiet looking workers whose claims upon the attention of visitors do not lie so much in their outward appearance as in their ability to do more and better work than horses—to “deliver the goods” both literally and in the popular parlance. The basement was never a beautiful place, notwithstanding the fine-sounding name of Exhibition Hall that has been bestowed upon it, its brick floors and walls and its bare beams and low ceilings giving little opportunity for decoration. For the present show, however, it has been transformed in a manner that was a decided surprise to visitors, the blue Dutch decorations on the walls having an exceedingly pleasing effect, somehow offsetting the low ceilings and making the brick floor seem quite appropriate. Plenty of light and the excellent arrangement of the exhibits, combined with the decorations, make the lower regions quite tenable, and the comparative quiet is decidedly grateful to business men who want to talk over matters with the truck builders.

Among the commercial vehicles exhibited in the basement there is a variety of types that is a little surprising, in view of the comparatively small total number of cars of this class shown. Honors are about equally divided between electric and gasoline vehicles, there being three exhibitors of each, excluding one exhibitor of motors only. Steam is not represented. So far as the actual number of vehicles shown is concerned, the electrics have much the best of it, there being eleven of these to seven gasoline vehicles. What the latter lack in numbers, however, they make up in interesting features and in variety of types; the electrics show practically no changes from what seems to be well established practice, if exception is made of improvement in the quality of the materials employed and in constructional methods. There is a very general tendency to make bodies as solid and serviceable as those used on horse-drawn trucks—this having reference more especially to the heavier ma-

chines—and to refrain from the very unnecessary and expensive process of putting a high finish on a truck intended for rough work. As a consequence the big machines are mostly of rather sober and businesslike appearance, which is quite in keeping with their character.

Gasoline motors of a number of types are employed to furnish propulsive power for machines, big and little. The types represented are the four-cylinder vertical water-cooled, four-cylinder vertical air-cooled, single-cylinder horizontal water-cooled and double-opposed cylinder horizontal air-cooled. Transmission systems include both planetary and sliding gear change-speed mechanisms—a two-speed planetary gear being found on the heaviest gasoline truck in the show as well as on the lightest gasoline delivery wagon. In final drives are double chains, single chains and, what is something entirely new in American commercial vehicles, a propeller shaft and worm drive. In frames the big trucks, both gasoline and electric, prefer channel or I-beam structural steel, with the exception of one large gasoline truck, which uses a very heavy and deep pressed steel frame. In smaller vehicles angle steel and steel-flitched wood are much used. Three exhibitors, one of gasoline and two of electric machines, fit their vehicles to be controlled from the left hand side, considering this a decided advantage for a commercial machine, especially if it is to be used in dense traffic, where close maneuvering is necessary. Tires are of solid rubber in all cases, even on light machines.

Among the electrics familiar constructional methods are followed, batteries being underslung and motors carried in the rear, and driving through either gears or chains to a countershaft, and thence by chains to the rear wheels. In one instance the motor is carried behind the rear axle. For heavy vehicles two motors are the rule, a single motor being used in light models.

Franklin.—An extremely interesting vehicle is the one-ton gasoline truck shown by the H. H. Franklin Manufacturing

A LINE OF PACKARD DEMONSTRATORS ON FOURTH AVENUE.

Company, of Syracuse, N. Y. This is a platform truck with a four-cylinder air-cooled motor of 12-horsepower placed under the high driver's seat, where it occupies no space that could be used for loading, but still is easily accessible through large metal grill-work doors in front and removable panels at the sides and rear. The motor is exactly the same as that of the Franklin Model D pleasure car, and is stated to be quite as economical in commercial as in pleasure car service. Transmission is through disk clutch and sliding gears, with final drive by propeller shaft and worm gear. This arrangement gives a very high road clearance with a low gear ratio; the gear used is of moderate size and the worm drives from the top. The pitch of the worm is rather steep, so that when the car is coasting the gear can drive the worm. By the use of high strength modern alloy steels the car has been made very light, weighing about 2,000 pounds and carrying the same weight. The Franklin wood framing system is employed.

Knox.—The Knox Automobile Company, of Springfield, Mass., shows two "waterless" delivery wagons with double-opposed cylinder motors under the bodies, cooled by the familiar Knox porcupine system. No important changes have been made in these vehicles since last year, though advantage has been taken of recent developments in the manufacture of alloy steels to obtain additional strength without increasing weight. The most conspicuous Knox exhibit, however, is the new automobile chemical fire engine, which is shown for the first time. This machine has already been described in *THE AUTOMOBILE*, but it may be said that it consists of a standard Knox touring car chassis with 25-30-horsepower vertical four-cylinder air-cooled motor, with two 30-gallon chemical tanks of polished brass mounted on the rear, together with small hand extinguishers, lanterns, axes and the tools and small articles usually found on such machines. The speed of the machine has been found of very great advantage in getting to fires, and the car has proved, in actual service, to be entirely reliable. There is a rubber-covered platform at the rear for two men to stand on. Solid rubber tires are fitted to the artillery wheels.

Pope.—Two electric vehicles are exhibited by the Pope Motor Car Company, of Indianapolis, Ind., manufacturers of the Waverley cars. One is a closed delivery wagon and the other an open vehicle with a box body of the express type. Steel-flitched wood frames are employed. In each of these machines a single motor is used, this being the company's practice in light models, though two motors are used in heavy cars. The motor is suspended centrally in front of the rear axle, and drives through double gear reduction and side chains to the rear wheels. Exide or National batteries are used, suspended under the flooring in the usual way. Steering is by wheel, placed on the left hand side, and the motor-controlling handle is also on the left. Steering

gear is of the rack and pinion type, and the wheel tilts. There are two brakes, one acting on a drum on the countershaft and the other an electric brake.

Studebaker.—The Studebaker Automobile Company, of South Bend, Ind., shows a line of four electric vehicles ranging from a very light delivery wagon to a heavy truck. The small wagon has a single motor driving to a countershaft and thence by chains to the rear wheels, while in all the larger cars there is a double motor system, each motor driving a short separate countershaft and a sprocket on each countershaft driving its rear wheel by chain. The Studebaker machines are controlled from the left hand side, wheel steering being employed in the heavy cars and side lever gear in the lighter models. These cars adhere, in the main, to the lines of last year.

Hewitt.—Three vehicles were shown by the Hewitt Motor Company, of New York, two being single-cylinder delivery wagons with inclosed bodies, arranged to slide backward to uncover the single-cylinder horizontal engine and planetary transmission gear, and one a 5-ton truck chassis. These cars are practically the same as shown last year at the Garden. The big truck, however, has been changed in some important respects. The general construction has been strengthened, and the vehicle, though rated at five tons capacity, is said to be capable of carrying seven or eight tons, the weight being 8,000 pounds. The motor, with four vertical water-cooled cylinders, develops 30-horsepower and drives through two-speed planetary transmission, propeller shaft and bevel gears to a countershaft and thence to the rear wheels by chains. The frame is a remarkably deep section pressed steel, and it looks fully equal to any load that could be placed on it, as do the springs, of the heavy truck type, semi-elliptic. Steering is by wheel on the left hand side, and the control wholly by foot, there being no side levers.

General Electric.—A number of electric motors and controllers of types used in commercial vehicles are shown by the General Electric Company, of Schenectady, N. Y., as well as several mercury arc rectifiers for converting alternating to direct current for charging storage batteries; the rectifiers were shown in operation, their weird bluish light attracting considerable attention. The motors, of various sizes, were of a kind used as standard equipment by a number of manufacturers of electric commercial vehicles, and, like most of the electrical equipment seen in the basement of the Garden, show little or no variation from lines followed for some time past.

General Vehicle.—In the vehicles of the General Vehicle Company, of Long Island City, it is notable that the pedestals heretofore used have been replaced by the more ordinary spring and shackle arrangement. These pedestals were made on the same principle as the blocks that guide the axles of a railroad car or engine in its vertical movements, and were characteristic General Vehicle marks. The manufacturers consider the more usual construction the best, and have therefore swung over to the majority.

A REVERSE CONTROL THAT IS INGENIOUS.

Along lines that find much favor is the exceedingly ingenious arrangement of the reverse control on the new Hotchkiss selective gear system. Only two longitudinal slots are provided in the quadrant, there being no special slot for the reverse. By the usual forward and backward movement of the lever in the two slots, the four forward speeds are secured, while the reverse is obtained immediately behind the low-speed position, in the same slot. On either side of the slot at this point are raised edges, against which a latch normally abuts, so that the low speed cannot be overrun. By raising the latch, however, a further rearward movement of the lever is permitted, whereupon it locks in the reverse.

HEWITT UNCOVERS AN EIGHT-CYLINDER CREATION

It was not until the complete list of makers who would exhibit at the Garden was made public that it became known that, while there would be no further additions to the advocates of the six-cylinder type of motor, there would be at least one representative of the eight-cylinder. This is the Hewitt 50-60-horsepower touring car, and, to judge from its external appearance with the bonnet down, it would never be thought to cover a motor having eight cylinders, as it is, in reality, inches shorter than a number of those on cars equipped with the standard type of four-cylinder motor. So far as the general design of the motor is concerned, Mr. Hewitt does not claim to have evolved anything startlingly new or radical, having taken the best standards of foreign practise as a guide.

Thus the cylinder castings are separate with the valves on one side, the motor as a whole practically consisting of two four-cylinder units placed at 90 degrees to one another on a crankcase of special design. This arrangement of the cylinders and valves permits of the use of a single camshaft which is centered between the two motors inside the crankcase. At its forward end, as shown by the accompanying front view of the engine, it revolves an upright shaft through bevel gearing. This shaft carries a combined timer and distributor at its upper end, and it in turn drives a series of small gear pumps of special design which are combined in the single multiple unit shown in a horizontal position close to the base of the standard surrounding the timer shaft. There are fourteen of these pumps, and each one feeds to

a lead supplying one of the principal bearings of the motor, giving nine drops per revolution to each. From the other end of the gear driving the oil pumps the shaft is continued rearward and employed to operate the magneto which is centered on the crankcase midway between the cylinders, a universal joint being used on this driving shaft to compensate for any relative movement. The magneto is a Simms-Bosch of the Renault high-tension type, and its position renders a minimum of wiring necessary. The order of firing is the same as that of two four-cylinder motors, the second of which explodes in inverse order to the first. For instance, the cylinders on the right hand are numbered 1, 3, 5, 7, and the left hand four 2, 4, 6, 8, which makes the order of firing 1, 8, then 5, 4,

and so on. The camshaft and its eight cams are integral.

The cylinder dimensions are 4-inch bore by 4 1-2-inch stroke, the motor developing its rated output of 50-60 horsepower at a comparatively low speed. The valves are 2 1-4 inches in diameter, giving a 2-inch clear outlet, and are covered with bronze valve caps, as are also the openings in the water jackets in the heads of the cylinders. The carbureter, which is of special design, is located between the right-hand units, considerable space having been left between the front and rear pairs on each side, the inlet manifold running down the center of the motor above the magneto. The flywheel is a basin-shaped, hollow casting about 16 inches in diameter, to which a spun steel cap carrying steel fan blades riveted to it is fastened. Complete, this flywheel only weighs about fifty pounds, and is made in this form to dispense with the necessity of a fan behind the radiator. An idea of the liberal dimensions given every part of the motor may be gained from the fact that the crankpins are 17-8 by 23-4 inches, though the motor complete only tips the scales at 590 pounds. Cooling is by means of a honeycomb radiator and centrifugal pump driven directly from the crankshaft.

The two-speed planetary gear which constitutes the transmission is also designed on the same generous lines, its weight of approximately 100 pounds making up for the lack of avoirdupois in the flywheel, though the power impulses are so close together in an engine with this number of cylinders that there is no necessity for great weight there. As will be plain from the

photograph illustrating it, this change-speed gear is carried longitudinally on the same sub-frame that supports the motor, final drive being by propeller shaft to a live rear axle. The steel constricting bands giving the low and reverse speeds bear against a series of fiber blocks slightly wider than the bands themselves and let into the periphery of the gear-containing case. The disk on the high-speed or direct drive bears against six helical springs let into the face of the gear box for a distance of about two inches, so that the motor is enabled to pick up the load very gradually regardless of the manner in which the clutch is engaged. An oil feed from the pump on the motor is carried back to lubricate the transmission. Control is by means of a system of interlocking pedals which may be locked in place

FRONT VIEW OF MOTOR SHOWING IGNITION, LUBRICATION AND PIPING DETAILS.

SIDE VIEW HEWITT SHOWING CYLINDER PLACING.

or released merely by the angle at which they are pushed, and which do not permit of the engagement of one gear without the release of the other, this being accomplished automatically. That is, when the car is running at any particular speed is not necessary to release the pedal corresponding to it before engaging another; merely depressing the latter throws the other pedals out of engagement before the new one can come into action. This makes a very effective form of control.

Light sheet steel is riveted between the main and the sub-frame throughout the entire length of the latter and the remainder of the mechanism is thoroughly protected by a steel pan which is readily removable. The differential is of the three-pinion bevel type, using nickel steel gears, this material also being employed in the crankshaft, valves, and other parts of the motor. The live axle is 1 3/4 inches in diameter and is supported on two 7-inch bearings. The wheels also run on very large bearings of the plain type, it being intended to replace these later with Timken roller bearings of large size. The differential case and rear supporting axle are stayed by a heavy strut and turnbuckle. The frame is of the usual channel section, pressed steel, heavily reinforced and stayed by cross braces. Brakes are fitted in drums on the rivers and are of the double internal expanding type. The wheelbase is 110 inches and 875 by 105 and 880 by 120 tires will be fitted front and rear, the car in complete running order tipping the scales between 2,900 and 3,000 pounds. Fitted with a standard type of touring body, the car lists at \$5,500. Whether considered merely from the motor point of view or as an entity, the car is an unusually creditable production and should prove about as silent and smooth a running machine as it is possible to build. It was rushed to completion for the show and further refinement of design will undoubtedly be made later.

HEWITT FLYWHEEL AND TWO-SPEED PLANETARY GEAR.

LIGHTING THE ROAD AHEAD.

Badger Brass Manufacturing Company.—The makers of the lamps "that show the way," have a stand full of the Solar acetylene headlights for the delectation of the autoist, who makes a round of the accessory makers' stand, to get pointers on the equipment of his car for the coming season. Correct design along lines calculated to produce the highest degree of efficiency coupled with satisfactory service, together with the long standing of these lamps on the American market, places them in the foremost rank.

R. E. Dietz Company.—As makers of lamps years before the automobile became a factor, at first the auto lamp business of this concern was but a small side line, but the demand for their special types has been so great that it has now developed to a point where it forms a very important part of their total output, as may be judged from the elaborate array of styles shown on their stand. All their lamps are built on the Sterling cold-blast principle, their limousine square models, for 1907, being particularly attractive.

Edmunds & Jones Manufacturing Company.—"E & J" lamps are the product of this firm, and their long standing in the automobile world is well reflected by the assortment of up-to-date styles they display. They have made a specialty of acetylene headlights, along original lines and their output has become so extensive within the past year or two, that the E & J lamps are known the country over.

Gray & Davis.—"We have always set the style," say Gray & Davis, in introducing their new model square carriage lamp type, for the season of 1907, which forms a prominent part of their exhibit. They have been vehicle lamp builders for a number of years back, so that it is easy for them to show how history has repeated itself in the evolution of the G. & D. lamp. In 1898, the two-light square carriage lamp of the candle type, was the vogue and remained so for some time. Then the automobile appeared on the scene, and for it something on the lines of the Continental locomotive headlight, which later grew into the "Bullet" type and then disappeared in favor of the square style now so much in demand.

C. T. Ham Manufacturing Company.—"Ham's famous cold blast lamps" is the slogan of this concern, and it is well reflected by the generous showing of various styles and types for different purposes that is spread out for the benefit of the visitor. Some of these to which attention is called, are the "Corona," the "Tourist," the "Apex," and "Monitor," all of them being adapted to burn kerosene oil, and are guaranteed to be of the type that neither jars out nor falls to pieces under any provocation.

Rushmore Dynamo Works.—Though its name was slightly misleading at first, this firm has become so well-known to the trade and the autoist generally, that its equivalent in the shape of acetylene searchlights and generators needs no introduction. The special system on which both the headlights themselves and the generators of acetylene gas are constructed, together with a painstaking effort to give the buyer the very best value that can be produced at any price, makes a Rushmore an investment that pays well in the end, though the initial outlay may be greater.

Rose Manufacturing Company.—"Neverout" lamps date back to the heyday of the bicycle, and thousands of them still adorn bicycles at this day, though the number of automobile headlights which have been produced in the interim, outshines them many to one. They are shown together with the well-known "Neverout" patent invertible safety gas producer.

Manhattan Lamp Company.—The chief model placed on display by this firm at its stand is their new flare front, all brass searchlight, which has just been placed on the market. They are made in sizes ranging from six to nine inches, equipped with both the stationary and swinging bracket supports. Other styles shown are French models, and the extensive line of marine lamps for which this house has long been famous, all of which are put out under the well-known "Saxon" trademark.

ONE CORNER OF THE GARDEN TIREVILLE.

ANOTHER SECTION OF ACCESSORIES GALORE.

WHAT THE TIRE MAKERS HAVE TO OFFER

TO the casual spectator the numerous exhibits of tires present much the same appearance year by year, and even those more deeply interested see on the surface but little that is new. The exhibits include, as a rule, a number of tires of the different standard patterns, several mounted wheels displaying the tires in place, and sections of tires showing the construction. So far as form and general method of tire construction are concerned, there is little change from year to year, but it must not be inferred that the tire makers are idle. The more stringent requirements of car users, due to increased weight and speed and more general use over roads of all kinds, keep the tire men busy in and out of season. Except in certain details, the result of this work is not visible at the show; it can only be appreciated by the user on the road.

The complete tire exhibit of 1907 includes first the pneumatic tire for touring and racing, then its humbler companion, the solid tire for commercial work. An auxiliary feature which is each year assuming greater importance is the "detachable rim," so called, which may as well be divided now into the two classes which it naturally forms; first, what may be called the "dismountable" type, in which the rim is taken apart to admit of the removal of the tire; second, the "detachable" type, in which the entire rim is separable from the felloe, or from an inner rim, being removed with the tire in place and immediately replaced by a spare rim with tire inflated on it. This new type, first heard of a year ago in the Continental races and seen here this year in the Vanderbilt Cup race, is rapidly coming to the front, many inventors being busy with it. Several examples are seen at the show, with others of the dismountable type.

Ajax-Grieb Rubber Company.—Quick change tire devices are receiving much attention from the inventor. It is generally admitted that for touring purposes the best device is one allowing the outer flange to be removed, to give an easy change of inner tube; for racing a dismountable rim, allowing an inflated tire fully mounted on its rim to be substituted for a burst one, is essential. Both cases are provided for by the models just brought out by the Ajax-Grieb Rubber Company. The dismountable outer flange is held in position on the rim by a spring band 1-2 inch deep and 1-4 inch wide, slotting into a groove on the fixed and movable rim. To dismount, it is only necessary to remove a small safety wedge, fitting up the opening between the two

ends of the spring band, contract this latter by means of a small lever and knock off the rim. The racing model is based on the same principle. The road wheel carries a fixed metal-faced rim with its inner edge raised. A movable steel rim, on which had been previously mounted a complete tire, is slipped over this and locked against side movement by an expanding band, like the one just described. To prevent creeping, the fixed rim has three grooves, into which lodge projections on the movable rim. Bearing, however, is distributed evenly over the entire rim. With this type special countersunk security bolts are employed. Under ordinary road conditions a tire can be changed in less than thirty seconds. The manufacture of a tire is also shown at the Ajax stand, the process being complete, except for the vulcanizing.

Continental Caoutchouc Company.—The regular Continental line is supplemented by a new non-skid tire for both racing and touring, built up in such a manner as to hold the studs firmly within the body of the tire. A new pattern of corrugated tire with flat tread is shown, and also the heavy tires, 5 1-2 inch, of which the company makes a specialty for use on cars of exceptional weight.

Diamond Rubber Company.—The growing prevalence of the dismountable rim has made evident the need for a special tire for such a construction, and this has been met by the new Diamond "quick-detachable" tire, of the flat-tread pattern and made with a very hard bead. Though specially made for the Marsh rim, this tire is guaranteed when used on three other special rims. There being no staybolts, a flap is built into the casing to prevent the bead rising under a side strain. The Marsh rim is shown, as fully described in THE AUTOMOBILE, also the Diamond inner tubes made without grain in the rubber. The other Diamond lines, including the wire mesh base and the side-wire type are shown.

Firestone Tire and Rubber Company.—The new safety universal rim is shown with changeable rings to fit contour of tire for all standard makes; the locking device of the split ring being simple and strong. The pneumatic tire of 1906 has been improved by the omission of the brass clips and the addition of a spreader which is controlled at the valve stem. A new standard clincher tire has been added since last year. The regular patterns of Firestone solid tires are shown.

G & J Tire Company.—The special section known as the

oval raised tread put out in 1906, with the tread oval instead of flat, giving an improved surface of contact, has proved successful in strength, durability, and efficiency and is continued as the standard line for 1907, both in the G & J and the Indianapolis Dunlop types. Specimens of the tires are shown, with the regular Midgley universal rim. The G & J motorcycle tires are also shown.

B. F. Goodrich Company.—The company's quick demountable rim, in universal sizes, is shown; the removable ring carrying a hook on each of its ends which engages in a slot in the flat rim. Without resort to lugs, clips, turnbuckles, screws and bolts, the tire is securely locked and all possibility of creeping averted. The clincher tires are also shown and the two styles of tread, the flat and the Bailey "Won't Slip." The Goodrich-Bailey is planned and made with a view to the solid anchoring of the studs so that they are held firmly with no tendency to work loose under the heaviest strains of hard roads and big loads. The Goodrich endless side wire solid tires for commercial vehicles are also shown.

ON THE RAISED PLATFORM, KNOX IN THE FOREGROUND.

Goodyear Tire and Rubber Company.—The regular lines of tires are shown, with little change from the high standards of the last few years. The demountable rim has been improved by a change in the locking ring, which is hollow and non-reversible; rings are provided for the Goodyear and the standard clincher tires. A novelty is the heavy tourist traction tire, just introduced, with a special arrangement of transverse grooves, spaced about three inches apart. This tire is built for hard work and wear, with a tread of half an inch of rubber, and the corrugations give increased traction in sand and mud. For a non-skid tire two circumferential grooves of square section intersect the transverse grooves.

Harburg Tire Company.—This American company handles the tires of the Harburg and Vienna India Rubber Company, of Harburg, Germany. The exhibit includes the usual line of clincher tires for touring and racing. The Harburg rim is of the detachable type; the steel rim holding the tire permanently and being itself removable from the main body of the wheel. In this way a pair of spare rims with tires not only in place but fully inflated and ready for use may be conveniently carried. In the event of a puncture the rim in

use may be removed by removing four nuts and slacking two others, when the rim may be slipped from its bed on the felloe. The extra rim and tire are slipped in place, the beveled faces of the felloe and rim assisting this operation, and the six nuts set up, completing the operation.

Hartford Rubber Works Company.—The regular Hartford line is shown in its full variety, of course including all the most recent features of tire and rim artificing. The demountable rim has been improved by the addition of a small but important detail, a worm gearing in connection with the central boss of the right-and-left screw of the turnbuckle, making the adjustment easy and rapid and also self-locking, as the worm gear cannot reverse. The demountable rim is shown in connection with the Midgley all-metal wheel. An important departure is the new Midgley wire grip tread, a non-skidding device. Five separate strands, each a helical spring about 3-16 inch in diameter, of hard steel wire, are firmly bedded in the tread of the tire, completely encircling it. As the outer surface of each coil or spring wears off, it leaves a series of small steel staples projecting from the rubber and gripping the road surface. There is nothing to throw mud or to cut the road, and no mass of metal to heat and destroy the rubber, but only the large number of small parts, each doing its work. The universal feature of the demountable rim is now perfected, the rings being reversible to fit different patterns of tires.

E. Lamberjack & Co., Inc.—The famous French tire is shown in all of its many makes by the company which has taken over the entire Michelin agencies of this country. The Michelin non-skid and the corrugated flat tread are the two makes particularly put forward, the excellent satisfaction given by both being considered a sufficient recommend.

Morgan & Wright.—This exhibit includes the usual line of automobile types of the clincher and Dunlop types with various treads, the De Luxe tires, and, as a new addition, a line of solid wire-strengthened tires for commercial vehicles, of various patterns and sizes, single and double.

Pennsylvania Rubber Company.—In tires proper the regular Pennsylvania lines are shown with no material change from last year, but two important additions have been made in a non-skid tire and a detachable rim. The new tire is of the Samson type but with special details of construction by which the studs are bedded in the center of the rubber, the outside leather merely steadying the outer ends of the studs. The detachable rim is composed of two steel hoops, one carried permanently on the spokes or the felloe and the other slipping over it. The inner rim is made with several slots or indentations in its circumference and studs projecting from the inner face of the removable rim fit these slots. When the rim is pushed into place the studs enter the slots and the outer rim is moved about an inch around the inner rim, thus locking the studs in their respective slots. The inner and outer rims are now locked against turning by two bolts through the felloe and inner rim, after which the outer rim and tire remain a part of the wheel.

Swinhart Clincher Tire and Rubber Company.—A well-arranged exhibit shows the various forms of solid tire with wire backing, including a mammoth 7-inch tire of the twin type on its rim. Two tires which have been in service for two years under a light delivery wagon are shown. A testing machine is used to illustrate the small difference between the Swinehart solid and the ordinary pneumatic tires; a hand lever is so arranged that the pressure of the hand on a small part of the tire surface is equivalent to the pressure on the tire in actual service.

New York Sporting Goods Company.—A new form of spring wheel, just patented by W. E. Schneider, is shown. It has oblong blocks of rubber, being arranged on end diagonally between the inner and outer rims; the device is not yet ready for the market.

Aster Company.—The "Pneu Electric" tires are shown at this stand with the other imported goods for which the company is agent.

Electric Rubber Manufacturing Company.—The Panther tire is shown, a wrapped tread tire, the company giving good reasons for adhering to this method of manufacture. There are also the Panther corrugated flat tread tire and the Panther and M. T. inner tubes. For heavy vehicles there is the Dewes solid endless tire.

International Rubber Company.—The new universal demountable rim now shown is simple and strong and does away with all bolts, screws and similar fastenings; the special clamping rings being readily slipped into place and in turn removed with a screwdriver or similar tool. Both the Bailey tread tires and the wrapped tread are made by a process of curing at one single operation, with a great improvement in quality. The various patterns of the standard clincher and other tires are shown.

this exhibit includes a new demountable rim; the main rim and outer locking rim being held together by a split spring rim of U-section grasping the inner flanges of both.

Samson Leather Tire Company.—The usual variety of this noted non-skid shoe is shown, of a special leather armed with steel studs.

Consolidated Rubber Company.—The Kelly-Springfield solid tire is shown in various sizes; this well-known tire long since reached a point where it might be considered standard.

Dow Tire Company.—A demonstration apparatus is shown. A wheel with pneumatic tire running under pressure on a flat steel pulley; the wheel is punctured by wire nails, but holds its shape with no sign of deflation.

Fisk Rubber Company.—A new feature is the detachable rim; the fixed inner wire is made with a flange on the inner edge while the outer edge is beveled. A split ring of spring steel is beveled to fit the inner rim, being held in place by six

Leather Tire Goods Company.—The Woodworth detachable tread is a non-skid shoe of chrome-leather and canvas, strongly built, with steel studs passing through their broad, flat heads in contact with the tread of the tire. Hooks of sheet metal are riveted to the edges of the shoe and these engage a ring of steel wire on each side. These wire rings are not truly circular, but crimped, and, being of tempered wire, they act as powerful springs to draw the shoe over the tire. The shoe is put in place by deflating the tire, when the hooks may be slipped over the spring rings. When the tire is again inflated the shoe is fast. The shoe need not be removed in order to change tubes. The device is built to prevent puncturing, to lessen the wear and to prevent skidding. A still newer form of tire armor of the anti-skid type is formed of a series of leather straps, each studded with steel rivets and placed across the tire about four inches apart.

Republic Rubber Tire and Shoe Company.—The Hercules leather non-skid tires and tire protectors are shown.

Republic Rubber Company.—In addition to clincher tires

set screws. The outer rim with its tire is readily slipped on over the split ring, which is then expanded as the set screws are set up, wedging it out until the inner and outer rims are firmly locked together. Fisk tires are also shown.

Motz Clincher Tire and Rubber Company.—The Motz solid tire is intended for pleasure cars, to replace the pneumatic; a new pattern is shown, with the sides undercut to give increased resiliency and the tread divided by a deep circumferential depression. Special advantages are claimed on sandy roads and also against skidding.

R. & P. Traction Tread Tire and Tube Company.—The traction tread tire is designed with a broad, flat face and inclined edges, the face being corrugated circumferentially. It is claimed that a greater protection from puncture is obtained with no liability to skid. The R. & P. duplex emergency tube is a combination of double inner tube and valve, the innermost tube of all being used an ordinary puncture.

Trident Tire Company.—The Trident tire is shown in the ordinary round pattern and also the flat tread pattern.

THE POPE LINE INCLUDES TOLEDOS FROM TOLEDO, HARTFORDS FROM HARTFORD, AND TRIBUNES FROM HAGERSTOWN.

IN THE EXTENSIVE REALM OF IGNITION

MAKERS of ignition specialties are responsible for what appears to be such a bewildering array of devices, often put forth under varying titles, that the average autoist is prone to look upon this more as a realm of mystery than otherwise. But when things are condensed, it will be found that, as a whole, the subject may be divided into a comparatively small number of heads, though the subdivisions under each are apt to be numerous owing to the number of makers who specialize in different branches. For instance, to start at the bottom, there may first be considered that greatest of all essentials, the source of current supply. Batteries, dynamos and magnetos sum this up, though it is necessary to specify dry and storage batteries, varying types of direct-current dynamos with special systems of ignition, and low and high-tension magnetos, which are also of varying types, according to their makers, in order to cover the subject more fully. Then there are coils, and here, in a single word, a wide range of apparatus is included, for as is the case with many other things, there are coils and coils. Timers and distributors form a division that is equaled by few others for variety and novelty, and it is something in addition in which great advances have been made. Then there are special ignition devices that partake of so many different characteristics as not to be capable of classification under any one head. Last but far from least there are the spark plugs and cable for connections. How much of the increased reliability of the modern automobile is due to the efforts of the maker of ignition specialties can only be realized, and that not wholly, by looking back a few years and recalling what ignition accessories were then and see what they are now.

DYNAMOS AND MAGNETOS.

Dayton Electrical Mfg. Co.—This company show their famous Apple dynamo and complete ignition outfit. This includes a storage battery, automatic cut-out switch for charging the same, and a combined switch and volt-ammeter. They also display a complete line of other ignition sundries, such as coils, plugs, etc.

Motsinger Auto Device Mfg. Co.—The well-known "Auto-Sparker," which is a small direct-current dynamo with a special governor attachment, is manufactured and shown by this firm. This has been on the market for a number of years and has given excellent satisfaction for marine and stationary work.

Remy Electric Co.—This firm shows its full line of magnetos for both low and high tension service. They also display a line of magnetos with oscillating armature for use on large stationary engines. Both the high and low tension magnetos are the standard equipment of several well-known touring cars.

Pittsfield Spark Coil Co.—In addition to a full line of coils, commutators and spark plugs, this firm shows a new line of high tension magnetos which they have just put on the market. All the working parts are completely inclosed, and the machine looks very durable and substantial.

Albert Champion Company.—Among the complete line of accessories and automobile parts handled by the Albert Champion Company, the Gianoli high-tension magneto occupies an important position. Simplicity and the essential quality of durability are combined in the Gianoli. It starts readily and after reaching 500 revolutions per minute maintains a constant tension, no matter how great the speed, thus doing away with any chance of burning out secondary or puncturing condenser. "Electric" automobile tires, comprising round and flat pneumatic types, anti-skids and solids, manufactured by one of the most important French firms, are another important line. Champion spark coils, Nieuport spark plugs, insulated cable, etc., are a few more of the many features.

C. F. Splittdorf.—This well-known maker shows his usual line of coils and other ignition sundries. In addition to these this year he is showing a line of high tension magnetos, including a small one for motorcycles. In this line is included a complete double system, including coil and switch.

Holley Bros. Co.—In addition to a full line of carbureters, including many special types, this firm shows the Holley magneto, including a double coil for an alternative battery system. The Holley magneto is on original electrical lines, which it is claimed make it much more efficient at low speeds than the ordinary magneto.

Leon Rubay.—This exhibit fairly swarms with novelties. All of the Lacoste goods are shown, including coils and timers. The special features are a full line of the Lacoste magnetos in operation and a small gasoline generating set for lighting country houses. This plant is shown complete, including switchboard and storage batteries.

Lavallette & Co.—This firm is the sole agent for the Eisemann magneto and shows a full line of the various types of machines, most of which are displayed in operation. There is also shown, in connection with this exhibit, about every possible combination of double ignition, both with one and two sets of plugs.

Robert Bosch, N. Y., Inc.—The well-known Simms-Bosch magnetos for every service, from the high-tension machine for motorcycles to the large low-tension oscillating types for stationary units of high powers, are displayed by this firm. All of these are shown in connection with models adapted to be operated by hand, and the exhibit is remarkably interesting to a student of the subject.

Sibley & Pitman—Show a very complete line of ignition sundries of various manufactures.

AMONG THE BATTERY PEOPLE.

American Electric Novelty Co.—This company show the "Ever Ready" dry battery and other "Ever Ready" electrical goods, such as gauge and speedometer light, etc., which are too well known to require description. It has brought out a combined clock, speedometer and odometer, very compact and known as the tourometer.

Eastern Carbon Works.—This firm displays its full line of standard dry cells and, in addition thereto, their new gas engine cell, which is especially designed for ignition purposes. The company is also showing a volt-ammeter which they warrant thoroughly.

Electric Storage Battery Co.—A complete line of vehicle batteries and ignition storage batteries is exhibited by this concern, their line being too well known to need description.

Franco-American Supply Co.—This concern displays the Look storage battery and also an extensive line of auto supplies, such as indicating bell pumps, Amco tire holders and the famous "One Minute" tire remover, which is demonstrated in a very satisfactory manner on the stand.

Gould Storage Battery Co.—These makers show a full line of their vehicle and ignition batteries. They are specially designed for the purpose for which they are to be used, and have been on the market for several years past, during which they have met with continued success.

Kitsee Storage Battery Co.—A full line of their sparking batteries are on view. For this type of cell special claims of lightness, large capacity and durability, as regards its efficiency, are made. Its neat carrying handle is a minor but noticeable feature.

National Battery Co.—A complete display of both vehicle and sparking batteries is shown by this concern. Their specialty is, of course, batteries for vehicle work, but their ignition batteries are well and favorably known.

National Carbon Co.—This firm makes the famous Columbia dry cell. Their line includes their standard dry cells and the special reserve dry cell. A special feature of this exhibit is the "Big No. 6" dry cell, which measures ten by twenty inches.

National Sales Corp.—In addition to a full line of sundries, the Royal battery, which had a number of interesting features, among which were a shock absorbing base, unspillable vent, non-corrodable binding post and automatic carrying handle, is shown by this firm. Their other lines comprise the Gaither-Owen carbureters and the Connecticut Telephone and Electric Co.'s coils and instruments, including the new gasoline dash gauge, introduced by the latter makers.

Semi Dry Battery Co.—The chief feature of this exhibit is the Jackson test board, which is designed to test ignition batteries comparatively under as nearly as possible actual working conditions. It is shown in connection with their special type of semi-dry cells.

Stackpole Battery Co.—This is a comparatively new concern, making its first bow to the public at a show this year. They specialize on five types of cells, each designed for a certain class of work, such as telephone, ignition and bell work, claiming that for each service a specially designed cell is necessary to obtain the most satisfactory results.

Vesta Accumulator Co.—This concern makes the Vesta accumulator, for which general all-around excellence is claimed. They also market an electric horn, which certainly speaks for itself, and also a very neat trouble-hunting lamp, which may be attached to the ignition batteries.

Witherbee Igniter Co.—The batteries "with the bee" are too well known to need any introduction. The complete range of regular types, which have undergone very little change since last year, is shown. A shock absorbing base of soft rubber has been secured to the bottom and this is said to add greatly to the life and efficiency of the battery.

COILS, TIMERS, DISTRIBUTERS, PLUGS, ETC.

Aster Co.—This firm exhibits a special French ignition wire made especially for high-tension work by the Société Industrielle des Telephones, of Paris. It is also agent for the Pneu l'Electric tire made by the same firm.

Atwater Kent Mfg. Co.—This firm shows its spark generator, which has been adopted as part of the standard equipment of a prominent touring car for this season. They also show a full line of their switches and meters. This season they have brought out a low-reading ammeter specially adapted for coil testing.

Autocoil Co.—This concern shows a line of coils of the interchangeable unit type. A specialty made by them takes

THOMAS SHOWS "FORTYS" AND "FLYERS."

the form of a coil box with an extra unit for emergency use. They also show a switch on the coil box to be used for changing over from battery to magneto, which is specially designed to be operated by the toe of the driver. Their four-unit coil, combined with a testing ammeter in the face of the case, is a recent specialty.

Other coil manufacturers are the Conn. Tel. & El. Co., the Byrne Kingston Co., the Pittsfield Spark Coil Co., and C. F. Splitdorf. These have been mentioned above.

T. Alton Bemus, Inc.—A specially designed distributor and timer, which is of the double-ball contact type, is shown by this manufacturer. As the only wearing parts on the contacts are the ordinary bearing balls, replacements can, if necessary, be easily and cheaply made.

E. M. Benford.—This maker shows a very complete line of mica plugs. A specialty is the racer plug, which is fitted in a tapered hole in the bushing, for which the mica insulator is a ground fit. This plug is fully warranted.

J. S. Bretz Co.—This firm shows the F. & S. annular ball bearings, of which they are the sole importers. This bearing is of the annular non-adjustable type and is provided with a separator and has special facilities for the removal and replacement of broken balls.

Byrne Kingston Co.—A full line of carbureters and mufflers for automobile and marine motors, of both the two and four-cycle type, is on display by these makers. In addition to this line, they also show a full line of coils which are designed on the latest and most approved lines.

Connecticut Telephone & Electric Co.—These makers have a complete line of coils and ignition sundries on exhibition, including a rather novel distributor and timer. One new wrinkle on its coil is the use of an adjusting screw with a graduated head. A novelty shown by this firm is a dashboard gasoline gauge, which is remarkably simple and effective in operation.

Duplex Ignition Co.—This firm shows the Duplex plug, the feature of which is the use of a small condenser contained in the porcelain of the plug and which will cause the spark to pass between the points, no matter how badly they may be fouled.

Heinze Coil Co.—These manufacturers show a complete line of coils, both for battery and magneto ignition. An interesting portion of this exhibit was a 24-inch spark coil in operation.

Herz & Co.—This firm shows a full line of its ignition specialties. It also shows the Paternoster shock absorber, for which it is the agent.

Igniter Appliance Co.—This concern shows the "Shur Fire" spark plug in actual operation, both with a magneto and battery, as a source of current supply.

Geo. Loring Co.—This firm shows the W. E. B. spark plug, for which it is the selling agent.

A. R. Mosler Co.—This firm shows a large line of special timers and distributors of its own manufacture. A novelty which it has just brought out is a combined porcelain terminal and plug protector.

Snutel Ignition Co.—A line of ignition apparatus of French manufacture, a rather interesting feature of which exhibit is a motorcycle coil that can almost be carried in the vest pocket, is displayed by this firm.

Uncas Specialty Co.—A very complete line of timers and distributors is displayed by these specialists. Two of their Leavitt distributors are shown constantly running, one in oil and the other in water. A specialty brought out this year is a roller type timer which has a special ground connection for high-speed work.

Wray Pump and Register Co.—The Lindsay timer and distributor is exhibited by this firm. This is remarkably compact, and a special point of novelty about it lies in the fact that it is protected with a heavy transparent glass cover.

LUBRICATION IS VITAL AND SHOULD BE THOROUGH

A. W. Harris Oil Co.—The various grades of special lubricants manufactured by this firm, such as the Excello gas engine cylinder, light-bodied cold test oil, A. W. H. gas engine cylinder, medium bodied; super gas engine cylinder, heavy-bodied; special super gas engine cylinder, extra heavy-bodied, and S. H. steam cylinder oil, each of which is shown feeding upward through glass tubes in order to illustrate the uniformity of its flow, and is also shown dripping on and flowing over a metal surface to enable those interested to examine the characteristics of the various grades. Beside these, there is exhibited trans compound, which is a fluid oil reduced to the consistency of grease for gear box lubrication.

John T. Stanley.—Special cleaning compounds put out under the trade names of "Mobo" and "Shofa" are the subjects of the exhibit of this manufacturer. "Mobo" is for the car and "Shofa" is to enable its driver to perform the same services for himself when grease and grime have become ground into his hands and ordinary soap and water are not effective.

N. Y. & N. J. Lubricant Company.—This firm makes a specialty of non-fluid lubricating compounds which are particularly valuable for winter lubrication when ordinary oils tend to get hard and stiff, though these non-fluid oils retain their consistency under any temperature conditions met with throughout the year. They are warranted not to drip, waste, clog or gum.

Havemeyer Oil Co.—Lubricating oils of varying flash points and fire tests especially compounded for automobile use are shown by this concern under the trademark of "Havoline," a name that is familiar to the average auto user owing to the success of these oils in continuous service.

Joseph Dixon Crucible Co.—Dixon and graphite have been synonymous terms for so long that the visitor knows what to expect when he sees the name of this firm's booth from a distance. The exhibit consists of the various grades of special graphite lubricants especially compounded for automobile work. In addition the type of brazing crucibles, now largely used by auto manufacturers, and Dixon's silica-graphite paint for metal are shown.

Adam Cook's Sons.—"Albany" grease, which is known the world over wherever machinery is used, is shown by this concern, who have been making this universally known lubricant for almost forty years. In connection with their exhibit they are distributing an interesting little pamphlet entitled "Auto Lubrication," containing considerable information of value to everyone who owns or runs a car.

Vacuum Oil Company.—There is probably no other firm in the business of manufacturing auto lubricants that has given as much attention to the subject of providing a special oil for each car on the market. The Vacuum Mobiloils, made in four grades, are each designed for a special purpose, and the company publishes an alphabetical list of American cars, giving the grade of oil recommended for use with it.

W. C. Robinson & Son Company.—This firm exhibits a full line of lubricating oils for every type of automobile and motorboat engine, as well as for general machine lubrication. They are put out under the trademark of "Autoline" oils, and are shown in a variety of grades and fire tests, each of which is compounded for a special service. A series of tests have been made of practically every machine on the market, so that the firm is in a position to recommend an oil for the user's car in every instance.

ONE OF THE MOST COMPLETE AND ARTISTIC EXHIBITS IN THE GARDEN SHOW IS THE BUICK DISPLAY.

TELLING HOW FAST AND HOW FAR

JONES SPEEDOMETER CO.—Jones, the man who builds speedometers, and has been building them since automobiles got to the point where they were fast enough to need them, calls for no introduction. He is always around when there is anything on, and he always brings his speedometers with him. History sayeth not, but somehow or other it seems as if Jones must have been the original man to show a speedometer in operation at the show. At any rate, he has them there now, lots of them, and the way the hand may be made to crawl steadily around the dial toward the "mile per" mark, or jump at it as if a policeman were coming along behind on a motorcycle, according to the way juice is fed to the little electric motor, is a sight that holds the visitor spellbound until he can almost imagine that he is at the wheel of the car that is running away.

Veeder Manufacturing Company.—Few things illustrate that old saw about the survival of the fittest better than the little Veeder—little because it was the smallest cyclometer that was put on the market. It was one of thousands, but, unlike them, it did not travel the same road as they and the bicycle did. Instead, it kept growing bigger, figuratively, until now it shines forth as the Veeder Tachodometer, though their predecessor, the cyclometer, is not forgotten as are its many competitors of bygone days. As has come to be the custom with this concern, its special instruments are all shown in working order. Standard cyclometers and a wide range of counters for various purposes are specialized by this firm.

Post & Lester.—In addition to its endless line of accessories, this firm shows the Stewart speedometer and mileage recorder. This instrument was designed by J. K. Stewart, president of the Chicago Flexible Shaft Company, a firm which for nearly twenty years past have made a specialty of flexible shafting. The case is a one-piece construction of heavy brass, highly polished and fitted with a four-inch silver-finished dial, the calibration being accurate and the figures so large that they can be read from the tonneau without difficulty. The scale reads from 5 to 60 miles, the delicate mechanism necessary to record very low speeds thus being dispensed with.

Charles E. Miller.—Following the plan adhered to with all the specialties that bear the Miller trade-mark, the Miller speedmeter was put to a thorough and lengthy test before being accorded this distinction. It is an extremely simple, compact and durable instrument, working on the principle of centrifugal force. The governor spindle is made from tool steel,

hardened and ground to size, the flyball and links being of brass, making it very accurate and sensitive. Crown gears are fitted for driving and the large gear for attachment to the hub is made so as to be readily fitted to the wheel of any American or imported car.

R. H. Smith Manufacturing Company.—The same attractive exhibit that helped to show the merits of the Springfield Motometer at the Grand Central Palace last month has been impressed into service at the Garden, and the steadiness with which the indicators of the several instruments that are shown in operation maintain their positions at a certain speed as long as the driving motors keep turning at the same rate is illustrative of the fidelity displayed by these speed and mileage counters in recording the distance traveled and the rate at which it is covered. The Springfield is quite unlike the majority of its competitors where appearance is concerned, besides which it occupies a very small amount of space and forms a slightly addition to the dash of a car.

Warner Instrument Company.—The recording dial of the Auto-Meter strikes the visitor's eye long before he gets within reaching distance of the stand of its makers. It has a long-distance face, so to speak, and though its containing case is one of the smallest of the kind employed for the purpose, owing to the special type of operating mechanism employed, it can be read clearly at many times the distance the driver of a car finds himself from the dash, so that there is no danger of confusing the figures. Magnetism is the controlling force of the instrument and the makers guarantee to renew any Auto-Meter found to be so little as 1-10 of 1 per cent. incorrect at any time within ten years after sale, barring damage from accident or "tinkerites."

Winchester Speedometer Company.—"Fine instruments for fine cars" is the motto of this concern, which is reflected in the character of its exhibit of speed and distance recorders. Centrifugal force is the basis on which the Winchester instruments are built, and they are built not only to do their work accurately but to last. In order to insure this before they leave the factory they are tested for accuracy for every mile of their range from one to sixty. Particular attention is paid to the driving, for upon this depends the service given. It consists of a flexible shaft made of wound steel English wire cable inclosed in a brass casing, the attachment to the case being from beneath, thus avoiding the objectionable short turn.

Oliver Instrument Company.—This firm manufactures the Index speed, trip and mileage indicator of the mechanical, cen-

trifugal type, which is the invention of E. C. Oliver, professor of mechanical engineering at the University of Minnesota. A vertical spindle carries an annular brass weight surrounding it and which ordinarily is maintained in an inclined position with regard to the spindle. Under the influence of speed centrifugal force tends to make it assume a position at right angles to the shaft, the motion being restricted by a spring bearing on a cam surface attached to the weight. According to its makers, the Oliver records everything but the events of a trip.

Hoffecker Speed and Mile Register Company.—Having been on the market for three years, the speed indicating and mileage recording instruments manufactured by this company are well-known to the automobiling public. The 1907 models have been improved in many ways to bring them to modern exacting requirements. One of the most interesting features of the new instruments for the coming season is a ball joint permitting of placing the dial at any angle to the dashboard of the car. The flexible cable is likewise so arranged as to overcome the objections hitherto urged against it in this connection.

Hopewell Brothers.—The Hopewell speed indicator is an accurate instrument, all the parts of which are made from a high grade of tool steel. It is made in two sizes, the smaller reading from 5 to 60 miles per hour and the larger up to 100 miles per

hour. It is capable of reading to within half a mile on any part of the scale, as the distances are uniform throughout the entire range. The instrument was shown in operation by a specially tested machine, giving all the ranges needed, so that its capabilities may be readily demonstrated.

S. Smith & Son, Ltd.—This firm is displaying the only English instrument of the kind offered on this market and which is shown here for the first time. A very complete series of styles is produced by this house, ranging from the smallest and simplest type of speedometer up to a combined clock, speed, trip and mileage recorder and annunciator, all of them enjoying a high reputation in England and on the Continent. They are all made with that painstaking attention to accuracy and durability characteristic of their country origin.

Motor Car Specialty Company.—"Because it is all one instrument" is but one of the claims put forward by the makers of the Lea Speedmeter as a reason for its superiority. The odometer is not an attachment but an integral part of the apparatus. An isolated mechanism not affected by jars to the case, counterbalanced gearing keeping the needle steady under all circumstances, and non-slipping gears mounted on a square shaft, constitute but a few of the advantages that account for its accuracy and consequent long-continued popularity.

RADIATORS, DASHES, FENDERS, ETC.

Briscoe Manufacturing Company.—From plain coil radiators, suitable for small runabouts, to the largest type of honeycomb radiator capable of cooling a 100-horsepower engine, is the important line of the Briscoe Manufacturing Company. Plain coils, coils in casing, coils of small tubes, staggered gang fin, flat tubing, and honeycomb are the principal types, but each one of these is constructed in several forms, giving altogether an almost endless variety of radiating surfaces. Fans are made in two types, one with plain bearing, the other with ball bearing. Blades are made of aluminum and may be either four or six in number for each type. Briscoe hoods are as varied as are the requirements of automobile manufacturers. Fenders also show a wide diversity of appearance even among the standard styles, while any special shape can be made. Aluminum fenders are also manufactured if desired.

Whitlock Coil Pipe Company.—This company is showing the new type of Mercedes honeycomb radiator which was uncovered for the first time at the Palace show in December. It is constructed of square, air-tight cells, separated by thin horizontal and vertical water columns. They are also showing something novel in the shape of a line of seamless welded exhaust and inlet manifolds and water circulating branches, the latter being of copper while the first named is of steel.

The A. Z. Company.—Radiators, metal dashes, mud guards, hoods, mufflers, tanks, sprocket steps, mud aprons, spark plugs, pumps, fans, and other metal fittings for the automobile are handled by the A. Z. Company. Radiators form the most important line; these are of various types and of almost every conceivable shape. Three standard types are the tubular, constructed with a series of tubes, no matter in what shape, whether flattened, crimped or fluted, which individually connect two or more water spaces; the cellular or honeycomb, forming numerous cells around the tubes, no matter if the tubes be round, triangular or square; the coil formed by a tube or tubes bent or coiled, with the water flow through same. Hoods, upon which so much of the external beauty of the automobile depends, are constructed in a variety of designs. Fenders, too, are equally varied in the standard shapes and can be obtained of any special form on order.

Metal Stamping Company.—This exhibit consists of cellular radiators with hexagonal tubes let into punched metal plates front and rear. It also includes a large line of fittings of various kinds, such as bonnet latches, etc.

BEARINGS OF ALL VARIETIES.

Timken Roller Bearing Axle Company.—Several new types of Timken roller bearing for automobile construction, have been prepared for the present season. Timken bearings for cone clutch and transmission, for steering pivot, where they give much greater ease of steering, and for rear shaft drive are particularly interesting types. Excellent I-beam axles, drop forged steering knuckles, spindles, connecting rod arms, and steering arms were shown on the Timken stand. The following cars exhibited at Madison Square Garden are using Timken roller bearings: Apperson, Autocar, Buick, Columbia, Franklin, Haynes, Hewitt, Knox, Northern, Oldsmobile, Packard, Peerless, Pope-Hartford, Royal Tourist, Thomas, Winton.

Hyatt Roller Bearing Company.—The distinctive feature of the Hyatt flexible roller bearing is the roller made from a strip of steel wound into a coil or spring of uniform diameter. The greatest advantage of this type of construction lies in its flexibility, enabling it to present a bearing along its entire length. A line of contact, as compared with points of contact in other systems, constitutes the superiority of the Hyatt. This type has been applied to every part of the automobile chain-driven rear axle bearings, shaft-driven rear axle bearings, hubs, sliding gear, etc.

Hess-Bright Manufacturing Company.—Ball bearings, first used on bicycles, afterwards tried on automobiles and found bad, later modified and found excellent, are now being more and more widely adopted. The Hess-Bright Company earned a reputation in this line and still retains it with their different types of ball bearings. Full type, silent type, step and thrust bearings for light loads and high speeds, for main and line shaftings, street vehicles, electric motors and dynamos, cranes, hoisting engines, and pumps, are all distinct models manufactured by this concern.

J. S. Bretz Company.—The Fichtel & Sachs (F. & S.) annular ball bearings handled by the Bretz Company, consist of two concentric rings or races, grooves in the races, steel balls running in the grooves, and a cage containing and positively separating the balls equi-distantly and keeping them in perfect alignment. This bearing is constructed of steel of an exclusive analysis. The F. & S. bearing is furnished either in the "silent" or "full" type. It may be employed as a radical bearing, taking the load at a right angle to the shaft, or as a thrust bearing by mounting to take the load parallel with the shaft.

SHOCK ABSORBERS ADD TO AUTO COMFORT

Diezemann Shock Absorber Company.—This concern shows a shock absorber which depends for its action on friction. This is obtained between a steel and fiber disk, lubricated by a liberal supply of Albany grease, which is contained within the casing of the device.

Hartford Suspension Company.—The Truffault-Hartford Shock Absorber is perhaps the best known of all shock absorbers, since it was the first to be introduced to this country. It is exhibited by this concern, which certainly has reason to be proud of its past performances. It depends for its action upon friction between disk-like surfaces, automatically lubricated by a special process according to the demands made upon it.

P. M. Hotchkiss.—The Hotchkiss Anti-Jolt Device depends for its action upon the principles of hydraulics. A cylindrical

is an opening in the piston connecting both sides of the cylinder. The size of this opening can be regulated by a needle valve which extends through the piston rod. This allows of easy adjustment for various weights of cars, as well as for varying conditions of service.

Herz & Co.—This firm exhibits the Paternoster shock absorber. This is a device which depends for its "dampening action wholly on friction." It operates through a pair of steel brake bands contracting upon steel drums. These work in a bath of glycerine. It is made so as to be adjustable for both up and down movements.

Kilgore Auto Air Cushion Company.—This concern has the distinction of showing the only pneumatic shock absorber in the show. This device is so arranged as to check both the down-

ESSENTIAL ACCESSORIES AND INVITING SCENERY AND THE EXHIBIT OF THE ROYAL MOTOR CAR COMPANY.

casing is divided into two parts by a radial partition, which is fixed and another to which an exterior arm is connected through a central axle. This part of the device is mounted on the axle. It is connected to the frame by means of an arm attached to the outer end of the axle of the device and a link. A fairly large check valve allows free downward movement as far as the device is concerned, but the rebound is controlled by means of a needle valve, which may be adjusted to suit varying weights of car and road conditions.

Gabriel Horn Manufacturing Company.—This concern shows the Foster shock brake, which consists of a small cylinder and piston, interposed between the axle and the frame of the car. The dampening effect is obtained by the flow of oil from one side of the piston to the other, controlled by means of a by pass.

Graham and Goodman, Incorporated.—This concern exhibits the Graygood Hydraulic Shock absorber. It consists of a small cylinder, closed at one end and having a stuffing box at the other, through which a piston rod works. At its inner end there

ward and upward shocks, and is also arranged so that this checking effect is graduated according to the amount of movement in either direction. The principle is that of interposing an elastic cushion between the axle and the body of the car, its tension or resistance being adjustable to exactly the point required to efficiently absorb every jar, so that it is not stiff and unyielding with the car light and too soft when loaded.

J. H. Sager Company.—This company shows its equalizing springs. These are a sort of supplementary springs which are used to check and control the action of the regular springs on rough roads by counteracting excessive movement in either direction, without at the same time interfering with the free play of the main springs.

Vestal Shock Absorber Company.—This concern shows the Vestal shock absorber. It depends for its action upon a friction collar and drum, between which is interposed a soft and easily replaced leather or fiber ring. A special point about this device is that it allows a small amount of spring play before the friction device comes into action.

SOME VARIED IMPRESSIONS OF THE SHOW BY "THE AUTOMOBILE" ARTIST.

PRESENT AND FUTURE OF A GREAT INDUSTRY

BRIGHT is the present and promising the future of the growing automobiled industry. Optimistic is the general tone of those engaged in manufacturing the motor-driven vehicle and its many component parts and accessories. Occasionally a skeptic is encountered, but he is only the exception that proves the general feeling of satisfaction at the outlook. In the opinion of many, automobile manufacture is only really begun in this country, and the quickness with which the outputs of the established concerns are sold to agents, who would not invest unless they were confident of the demand in their respective vicinities, tells its own story. Coincident with the coming of the automobile has been the pronounced call for the improvement of the roads, and this same rebuilding of the highways is going to result in the sale of many more thousands of cars, for the farmer is awaking to the value of the automobile, is buying now, and will buy in greater numbers in the near future. Read the comments of those in and out of the trade on the present and future of the greatest industry ever established in this or any other country.

DISTINCTIVE, STABLE, UNIQUE INDUSTRY.

By M. J. BUDLONG,

PRESIDENT ELECTRIC VEHICLE COMPANY.

The present status of automobile making certainly stands unique in the history of industrial enterprise. Twelve years ago hardly any automobiles were in use. To-day it is estimated that the value of cars in the hands of purchasers exceeds \$200,000,000. On this side of the water this diversion of an immense amount of capital into a new channel has mostly taken place within five years, and so naturally and smoothly as to cause no particular stress in any direction. Now and then a purchaser may have mortgaged his house when he ought not have done so, but it is strikingly evident that the great majority of cars in use in the United States belong to owners who can afford to have them; and this fact points strikingly to the wonderfully prosperous condition of the United States at the present time. As for the future, the industry can look the new year in the face without flinching and all indications are toward prosperity for several more years to come. The advance bookings for 1907 deliveries break all previous records. Not only is the popularity of motoring keeping pace with the ability of the manufacturers to supply the demand for cars, but motorists are taking a more sane and conservative view of automobiling than ever before, which is an especial indication of the permanent stability of the industry. The principal obstacle in the path of recent progress has been accidents, 95 per cent. of which were purely avoidable. There is now everywhere manifest a tendency to frown down recklessness and the work of ignorant operators; and this perhaps more than any other one thing will make for rapid increase of sales in the future.

GOOD ROADS AND GOOD TRADE GO TOGETHER.

By ROBERT P. HOOPER,

CHAIRMAN A. A. NATIONAL HIGHWAYS COMMITTEE.

It looks to me as though the prospects for the sale of new cars will continue as long as the public is making money as fast as it is now. The point that is particularly favorable to all automobilists is the fact of the large number of machines that are being purchased by the farmers and all classes of people living in the outlying districts. Already we see a very marked evidence of a friendlier feeling toward automobilists than has ever existed before, and I believe that the automobile owners are working together to help add to this good feeling, to a very much greater extent than they have ever done before. Further, there is no doubt that the adoption of the automobile by the farmers has already created a demand for roads, which we could never have secured in any other way. We have no difficulty whatever, at the present time, in securing favorable expressions of opinion in regard to good-roads laws, and also promises of help from men that have been antagonistic to us for a long time past.

DEMAND INCREASING FOR GOOD AUTOS.

By H. M. SWETLAND,

PRESIDENT CLASS JOURNAL COMPANY, PUBLISHERS "THE AUTOMOBILE."

The outlook for the industry is most encouraging. The demand for well built automobiles of every description is increasing rather than diminishing. The sale is still hampered to some extent by unjust garage, repair and supply charges, but these accessories to the industry are being conducted on a more substantial basis, and the "get rich quick" factor is being slowly eliminated. Uniform standards of parts in the various types will now follow as in railway equipment, and better material and workmanship will mark the progress of the year.

The buyer is becoming educated and more discriminating, and cars of all classes will be selected with more consideration of adaptability to the special requirements. Touring cars will not be bought for runabout service, and runabouts will not be purchased for delivery vehicles, all of which will tend to the greater satisfaction of the purchaser. For all special services, particularly special commercial uses, automobiles will be constructed from plans and specifications in which the requirements will have been considered from a standpoint of advanced engineering.

The fact that the industry is on a sufficiently substantial basis to attract our most influential and progressive engineering ability, as well as abundant capital, is proof of the possibilities and permanency of the industry. We only need to continue high-grade construction in all lines, give the user honest consideration during his educational epoch, and avoid provoking drastic legislation by reasonable use of public property. The future then is beyond any question.

MAGNITUDE OF PRODUCTION A FACTOR.

By HENRY FORD,

PRESIDENT FORD MOTOR COMPANY.

American supremacy in the automobile industry must be won, as in other branches of international commercial competition, by following American methods and doing business on the scale to which we are accustomed, and which to our foreign competitors seems of almost impossible magnitude. In locomotive building, bridge construction, railway and steamship enterprises, and in other branches, Americans have outstripped all competitors by the magnitude of their operations. The scale on which we Americans do business is made possible by our faculty of reducing the most difficult and seemingly formidable problems to the simplest and fewest terms—by so designing that every operation from first to last will be as simple as may be and making as many parts as possible standard in form and size and therefore interchangeable. Strange as it may seem, an American bridge building concern can furnish an estimate on a bridge to span a river in South Africa, and need not even know the width of the river or the height of the banks. Three cents and a fraction per pound is the

price of bridges—the amount it will weigh depending on the various dimensions, which latter have long since been worked out and reduced to simple tables. Looks easy when you think of it, and yet our foreign competitors have never been able to reduce bridge building to those terms—nor to compete in estimating on a bridge job with Americans. In locomotives it is the same. Even watches come under the same head—and the automobile comes between the two, combining as it must the strength and power of the one, the accuracy of the other. Some years ago the Swiss government sent an emissary over here to investigate and report on the watch industry, the American product having then only begun to cut seriously into the revenues of the Swiss national industry. He was an honest emissary—and a worthy one, since he believed it better that his people should know the truth, even if that proved unpalatable, than a more toothsome fabrication which should in the end be expensively misleading. His report was to the effect that the Swiss attitude toward the American product was wrong. That the belief that the Yankee product was inferior as well as cheaper was a superstition born of racial prejudice. And he stated frankly that his investigations had shown him that the hand-made Swiss product could not even approximate the accuracy of the machine-made American watch. They must then adopt American methods or suffer in the competitive field. Result, watches made in Massachusetts are now sent to Switzerland, reshipped to America, and sold to Americans as “imported” time-pieces.

We have a very great advantage over the foreign maker even when he has adopted, as nearly as he can, our own methods. He cannot hire American workmen—men of a higher intelligence, because more self-reliant, self-respecting and more ambitious. It is a penalty the older countries must pay for long years of oppression and suppression of their people. The German is a better worker in America than he was in Germany, the Frenchman than in France, the Irishman than under British rule. We get the benefit of all that.

As for the future of the industry—that is assured. There is apparently no diminution in the demand, and as cars are made in greater quantities and prices correspondingly lowered the market is enlarged immeasurably. There has not been a month in the year that the Ford factory has not been behind its orders—this applies to our high-priced six-cylinder model as well as to the four-cylinder runabout. Perhaps that is due to our having adopted at an early date a policy which we knew the future would make necessary—I do not know. Anyway, I believe the industry has just begun to develop, and he would be bold indeed who should predict that the business has reached its zenith or that a serious decline will begin during the lifetime of men now living.

FUTURE ONE OF SPLENDID POSSIBILITIES.

By G. V. ROGERS,

SECRETARY MITCHELL MOTOR CAR COMPANY.

The subject of the automobile industry is one that, try as we will, it is impossible to view it in any other than the most optimistic light. It seems to us that the possibilities of the automobile have developed more, and have been more generally understood and appreciated, within the past twelve months than during its entire previous life. They are not only used to-day for work thought beyond their capabilities, but they are making undertakings possible that were undreamed of and impossible without their aid. In other words, their advent is creating a demand for themselves unknown heretofore, and the possibilities of which we can only dream. There is no doubt but that there is a shortage to-day and that the country could absorb twice the number of cars that will be made during the year of 1907. Within ten years it will be one of the four largest industries of the country with the most rapid growth, not even excepting railroads, that the world has ever known.

MORE DIFFICULT TO PRODUCE THAN TO SELL.

By ALBERT L. POPE,

VICE-PRESIDENT POPE MANUFACTURING COMPANY.

In the present state of the industry it is more difficult to produce good cars than to sell them. The demand is strong for such machines as have won in past seasons a reputation for dependability and efficiency, and at the same time purchasers are not easily attracted to makes of unknown quality. If this analysis is correct there certainly is a market for all the good cars of 1907. Without question the automobile business is firmly established, and pleasure vehicles will continue to increase in popularity and general use for some years to come, a condition of affairs that is bound to insure good roads throughout the entire country. By that time the commercial vehicle in its various forms will have reached such a state of development that it will in a large measure replace the horse-drawn cart, at least in congested centers of trade.

New uses for the automobile are constantly being hit upon. One of the cleverest that has recently come to my attention is the plan of using an automobile as a part of the equipment of a bank, to deliver moneys to customers and collect deposits from them. This is a good business policy, and in line with the developments of the age. It naturally follows that the bank which gives the best service to its patrons will get the largest amount of business. Why should not the banks go out in this way and bid for an increase in their line just as merchants and manufacturers do?

CONSERVATISM IN DESIGN A SAFE FACTOR.

By E. H. PARKHURST,

VICE-PRESIDENT PERRIN MOTOR CAR COMPANY.

The automobile industry in this country is on a very satisfactory basis, and will undoubtedly remain so as long as the present conditions of commercial prosperity continue. The tendency is still toward the high-powered cars of large seating capacity, whereas abroad there seems to be an increasing demand for the lower-powered cars, particularly for the closed type. It is probable that in America it will be necessary to use cars of higher power than are used abroad because our road conditions require it. At the same time I believe that in the future there will be some readjustment of public sentiment, and that cars of smaller horsepower than we are now making will come into favor. It is a fact that we use cars mainly in the city, where excessive power and speed are a distinct disadvantage, as it involves longer cars, heavier cars and a higher cost of maintenance.

The public does not regard freak or experimental cars with favor, and has come to understand that conservatism is safer and that a good car is not the result of chance, but on the other hand is the product of good design, good material and good workmanship, and after that the elimination of weaknesses and bad features that are found out only through experience.

Although there is at present considerable interest shown in the six-cylinder type of car, it should not be supposed that this interest amounts to dissatisfaction with the present four-cylinder type. There is much that the public wishes to know with respect to six-cylinder cars, and much that must be proven by their makers before there will be any general demand for them, but I think that now they are regarded as somewhat of an experiment.

The great demand for the pleasure type of automobiles has prevented, and will prevent for some time to come, the development of the commercial car. The importance of the field for commercial vehicles is not being overlooked, however, and when the supply of cars more nearly equals the demand, or when the demand may fall off, there will certainly be a rush on the part of all makers to build commercial cars.

THE LAW OF SUPPLY AND DEMAND.

By GEORGE E. FARRINGTON,

TREASURER AMERICAN AUTOMOBILE ASSOCIATION.

Supply and demand is the never-changing basis of commerce and industry, regulating prices and quality as well as quantity. It has been interesting watching the effect of this law in the automobile industry. For pleasure machines it seems as if the supply had about reached the demand, and would soon pass it. This will mean still more attention to surpass in perfection of finish and construction of the motor, as the principle of operation seems to be nearly perfect, as are the passenger accommodations. Therefore we can assume that competition with the decreased cost of manufacture of parts, and that the user will be no longer called upon to pay heavily for experiments of the builder and cost of selling, will result in much lower prices for better material and, therefore, machines. The haste to manufacture to meet the demand is the principal reason that the domestic cars have failed so far to meet the finish, workmanship, and wearing qualities of the best imported cars, and again our labor and material are and have been much higher in cost than abroad. Competition will soon make it imperative for us to meet the standard of the best, which we can do.

The wise manufacturer of automobiles is to-day giving much time and attention to the commercial vehicle. This is a field without limit. Speed, durability, cost of maintenance, regularity in good or bad weather, excess of load, less space occupied, and the saving of the horse, who so often suffers through brutality, overwork, and overload, are unanswerable arguments.

A RATIONAL TENDENCY IS OBSERVABLE.

By F. L. SMITH,

VICE-PRESIDENT AND GENERAL MANAGER OLDS MOTOR WORKS.

The most healthful sign of the times for the automobile manufacturer, and for that matter to the distributor or agent, is the fact that the craziness of the whole game is rapidly passing away. The experienced buyer to-day does not attach the old importance to the magical word model, as applied to the machine made and delivered in one year as against the previous year's output from the same factory. A car that is good to start with in any given year needs only to be kept up to date in the little detail matters that make for the safety, comfort, and peace of mind of the owner and driver, and the limit is also being rapidly reached in the absurd and useless additions to simple mechanical parts, which ought to be enough to keep the average layman busy learning his machine and understanding that as long as he has to do with a power plant on the flowing road it is well not to let his mind run away with the dazzlements of extra fixings, double-jointed action, and forty-odd complications, to effect a very simple move which the driver-owner these days is qualified to master without much mental strain.

If you take the evolution of the single harness for a horse you will discover that straps, buckles, and all the working parts are made of the best material and as simple as it is possible to make them, and that they are cut down to the fewest number—not for the sake of economy, but for the sake of the man that has to hitch the horse and drive him. You might as well take pleasure in the invention of an automatic attachment to fasten around your waist, and by tripping a trigger in your right hand vest pocket automatically remove your hat and salute a passing acquaintances to save the mental labor of performing that courtesy by means of the thumb and forefinger acting in conjunction with your elbow joint and full arm.

The whole trade is getting extremely sensible these days, and it is not the novelties and the strange stunts that people lie awake nights to think of that appeal to the buyer—which is, in a word, to say that straightaway excellence in material

and workmanship, backed by good records and good friends, is a final proof of a good automobile as it is of every other commodity commercially dealt in in these great United States. There appears to be room for everybody that makes a strictly first-class machine and sells it honestly. For the rest it is merely a question of the frequency with which angels are met to foster the existence of yellow dogs who have no real reason for being. All of which has come about by the sober second sense of the American buying public and not by any crafty effort on the part of manufacturers or selling agents. It is also to be noted that the strong trade papers, and the most progressive, have been extremely conservative and sensible in their views as to the development of the industry. Altogether the automobile manufacturer has much to be thankful for on the beginning of the year, not the least among which is the above-mentioned general prevalence of a rational outlook on the whole industry.

AUTOMOBILE'S PLACE FIRMLY ESTABLISHED.

By STANFORD L. HAYNES,

EX-PRESIDENT AUTOMOBILE CLUB OF SPRINGFIELD, MASS.

The automobile, it seems to me, has already firmly established its place in the world.

Its popularity as a means of pleasure is without a question.

As a means of utility, from my own experience, I know I should find it extremely difficult to accomplish the work I am called upon to do without it, and for a light delivery service with which I have had personal experience in my own business I know that one car will do the work of three horse-drawn vehicles—do it economically, and with better despatch. During our recent holiday rush of business one car has made as high as five hundred deliveries for us in one day, covering a distance of over seventy-five miles.

No physician to-day, having a practice requiring three or more horses, can afford to use them, as one good car, with a competent man to operate and care for it, will reduce his time in making calls at least one-quarter, and a busy doctor's time is certainly valuable. From my observation, however, he should not try to care for and operate his own car.

I am looking forward to the day when we can have special rights of way for the automobile between the larger cities so that a business or professional man can leave his own office at any hour that suits his convenience best and arrive at his destination in his own conveyance, entirely independent of the railroads and at no great loss of time, if any. If such rights of way were established I am confident they would pay for themselves even to-day, as the convenience offered would be highly appreciated by many a business man who would willingly pay any reasonable charge for the time saved and the convenience gained. I trust some move may be made in the near future toward the establishment of such rights of way that the automobile may more fully fulfill its mission.

THE TENDENCY TOWARD SIMPLICITY.

By CHARLES E. DURYEA,

PRESIDENT DURYEA POWER COMPANY, INCORPORATED.

I always thought I had a pretty big idea of the future of the auto business and my friends agreed with me on this point, but I confess that it is growing beyond my expectations. I am surprised and pained to see the growth toward cumbersome, complicated vehicles, although I know it is a matter of history that progress is made from the complex to the simple and that the large, clumsy, overgrown affairs ought to be expected first. I am sure that the future will develop simple, powerful, serviceable vehicles, more so than can be found at present, and that the use of these vehicles will extend to the masses just as did the bicycle.

More specifically, I saw signs of simplicity in the designs of vehicles exhibited at the last show. The combining of the trans-

mission gear with the differential gear box on the rear axle groups the mechanism in two places instead of three and gets a greater proportion of the weight on the rear axle—a move decidedly proper. The success of several vehicles having the motor at the extreme rear is a straw showing what will happen to others with like placing. There is more room for the motor at the rear than at the front, the weight is more effective, the power is transmitted with less loss and the passengers may be moved slightly forward, so as to be carried between the wheels with greater comfort. This seems to me the next design in automobiles. The motor went to the front to secure accessibility and cooling, but the cooling can be had at the rear, and the room at the rear for accessibility is greater. I believe the public are appreciating more and more light weights and large tires, and this combination is the solution of the tire trouble. Incidentally large wheels also serve to smooth rough roads, and rough roads, unfortunately, are the American kind.

COMING ALONG, BUT NOT IDEAL.

By W. S. GORTON,

SECRETARY AND GENERAL MANAGER STANDARD WELDING COMPANY

At the present time the greatness of the "great" automobile industry is largely displayed in the columns of a great number of so-called automobile journals, most of which are simply reprints of old matter and photos of machines directly advertising some one product. Of the business, would say, that in the judgment of the writer it is improving materially and bids fair to assume very large proportions with the successful introduction of the commercial vehicle.

Great improvement has been made in the general mechanism of the car during the past year as to strength, reliability and convenience of operation and repair, but it is still far from the standard of excellence which must be arrived at before the motor car can become an altogether popular vehicle. When the ordinary automobile can be used with little fear that anything will go wrong except the rubber tires, it will have a great many more advocates than it has at the present time, as well as users.

If the work which is now being carried on toward the perfection of suitable highways for automobile use and other uses carries through, great credit must be given the automobile industry for bringing about a condition which is so much needed, especially in the central, western and southern portions of this country, where good roads in some sections are practically unknown for six months in the year. If the automobile can bring about the molding of public sentiment in this direction, all the time and means that have been expended upon this interesting and acceptable method of transportation will be well placed and prove of great advantage to the country at large.

SOUNDNESS AND STABILITY IN FUTURE.

By H. E. RAYMOND,

VIC-PRÉSIDENT THE B. F. OODRICH COMPANY.

I can only voice, what is undoubtedly the universal consensus of opinion, that the future of the automobile industry is tremendous in possibilities. The present can be aptly criticised for its extravagance in detail and wholly impossible surrounding features of unbusinesslike methods of procedure. This is not due to lack of business management, but to the swift moving events that have carried the industry to a feverish point before mental activity could assimilate it. The future will see a readjustment of methods and consequent soundness and stability that will really mean much more to the trade at large than the present seeming prosperity, which involves the error of judgment now prevailing. There is nothing alarming in present conditions, which might, however, be termed the cock-tail to the drawing of the more solid business lines to come.

MATERIAL MAKERS HAVE BEEN SWAMPED.

By E. D. FRETZ,

SECRETARY AND TREASURER LIGHT MPO. AND FOUNDRY COMPANY.

As every one well knows, the automobile industry is pushing forth in leaps and bounds, unprecedented in its growth, so that accessory manufacturers have not been in position to build additions to increase facilities rapidly enough to meet the urgent demands made upon them by automobile manufacturers for prompt service. While the automobile industry in all its details has grown very rapidly, it is our opinion that the industry is only in its infancy and that there will be little abatement within the next three to five years.

In our own line, as manufacturers of aluminum, manganese bronze and bearing metal castings, we have not been in position to measure up within fifty per cent. of the heavy demands made upon us for our product. The rapid growth has used up raw materials so fast that the producers are unable to supply the demand, and they, in turn, are spending millions of dollars to bring the supply of raw materials within the current demands of this great industry. Although we have large facilities for supplying castings, as far back as last September it became apparent to us that we could not take care of the many demands upon us and have been obliged to turn away many applicants with orders for our product, believing that it were better for us to give satisfactory service to a limited number than to attempt to supply an unlimited number. The future to us looks good, although competition is very keen. We are of the opinion that all honest manufacturers will have all they can do for at least from three to five years.

MAN FROM MISSOURI HAS BEEN "SHOWN."

By ROY F. BRITTON,

SECRETARY-TREASURER ST. LOUIS AUTOMOBILE CLUB

I speak from the standpoint of a Missourian. This State seems to be in a peculiar situation. Missouri ranks fifth in population, seventh in wealth, and eleventh in the number of automobiles. Probably this is accounted for by the bad roads in certain sections of the State, but I think our unreasonable law has had more to do with it. For the past four years autoists in Missouri have been required to operate their cars under a law limiting the speed to nine miles per hour and requiring the payment of a \$2 license fee in each county. This is practically prohibitive, and I think that under the circumstances the automobile progress that has been made in this State is remarkable.

From present indications it seems that the coming season will be the biggest one in the history of automobiling in the country. An extraordinary number of machines for 1907 delivery have been sold in St. Louis. We have every reason to believe that our Legislature has recovered from the attack of "autophobia" which it suffered in 1903, and will give us, at its next session in January, a fair and reasonable law that will tend to promote better conditions. As a matter of fact, I think we are really just beginning to get into the "game" out here, and I have great expectations for the future.

A YEAR OF GREAT PROSPERITY PREDICTED.

By VAL. DITTENHOFER, JR.,

PRESIDENT CINCINNATI AUTOMOBILE CLUB.

Automobiles have really only begun their great work, especially in our city, and from all indications there never will be so prosperous a year as the one we are now entering upon, for the majority of the people are talking new machines. Not only will they be used for pleasure, but also by business houses, all classes of which are now taking a great interest in the development of machines for commercial purposes. Taking it all in all, I think prospects of this great industry are more than encouraging for the present year.

THE AUTO AS A COMMERCIAL FACTOR.

By H. A. GRANT,

MANAGER ADVERTISING DEPARTMENT MAXWELL-BRISCOB MOTOR COMPANY.

The question is often asked, Will the automobile follow the bicycle? There are two excellent reasons why it will not. The first, the bicycle was never a factor in commercial life. It is true that it was used quite largely in transporting individuals from place to place, but it had no bearing on the commercial life of the large cities. The automobile delivery wagon and automobile truck are fast replacing the horse-drawn vehicle for fast service, and it will relieve more than any other one thing the present congested condition of our great cities. It will also enable the streets to be kept in a more sanitary condition.

In the pleasure vehicle line there is no reason or indication why they should not be as popular in years to come as they are at present. The automobile has brought back the old coaching days and has been the means of developing good inns throughout the country. It was only three or four years ago that a good hotel outside of our large cities and a few of the largest towns was a rare occurrence; now there are many fine inns that owe their existence almost entirely to automobile parties. England and France are still ahead of us on good roads and good country hotels, but it is gradually being changed, and as the automobile becomes more used by all classes, just so soon will we have good roads and good inns throughout the country.

GOOD ROADS THE INDUSTRY'S HOPE.

By S. D. WALDON,

SALES MANAGER PACKARD MOTOR CAR COMPANY.

The future of the motor car industry is dependent, to a great degree, upon highway improvement. Good roads propaganda and then quick, effective, extensive practical work in the making of roads are what count in firmly building up the motor car business. The Packard Motor Car Company has absolute faith in the permanency of the motor car business and is looking to the future for its profit. It also realizes that one of the best opportunities for creating a general faith in the permanence of motor cars as road vehicles lies in good roads work. The automobile industry must not expect profit now. The future is of too great consequence to allow it to be scorched with hot air methods intended to yield immediate return. Thus may the industry better itself most by never-ceasing endeavor focused upon the future; thus may the automobile industry do itself direct and lasting good by doing whatever and as much as it possibly can for better highways in this country. When the highways of America equal those of the popular touring countries of Europe, then may we readily expect America to be at the top of the heap in international motor car trade.

OUTLOOK IS VERY ENCOURAGING.

By J. P. COGLIN,

PRESIDENT WORCESTER AUTOMOBILE CLUB.

From the manufacturer's standpoint it would seem that the sales for this year would exceed those of any other without a question. The manufacturer appears to be better prepared than ever before to meet this condition, as the 1907 models have been on the market for some months in a great many cases. The tendency seems to be toward larger horsepower, while the style and type seem to have been mixed.

With reference to roads, there is great interest created by the Long Island Parkway. We have indications that something may be done in that line in New England. There is no question but what automobiling has caused a lot of agitation for good roads, and that results are being accomplished. There is also some question as to whether automobiles impair State roads as much as horses. It would appear that it was

the combination of the two that was destructive; that a road used exclusively for automobiles will not tear up nearly so fast as when a horse and narrow wheels go over it, which tends to cut the surface. We will have this measure before us undoubtedly to contend with in the Legislature this winter.

It is not the purpose of the Massachusetts State Automobile Association to propose any legislation this winter to any extent. The ground will be taken that the present law has not yet been fully tried out. However, it is proposed to watch for bills detrimental to automobile interests, and if any are introduced will oppose them.

A SURVIVAL OF THE FITTEST.

By M. L. GOSS,

SECRETARY BAKER MOTOR VEHICLE COMPANY.

The new year opens most auspiciously, the sun light of prosperity illumines the outlook, the public interest in automobiles is intensified beyond any previous experience. There is promise of a quick market for quality and possibly good business for bad and some sales for the indifferent, but still I believe that 1907 is to prove a crucial period of the business. It is the beginning of the elimination, the primitive days have passed. The crude first machines (and they all look alike to the public) were more fascinating than the telegraph, telephone, phonograph, electric light, camera and all other of the new inventions of the nineteenth century. These old machines have gone, we hardly know where. The people have grown more wise, more mechanical, more discriminating, and now differentiate between automobiles of reputation and distinctive characteristics of quality from cheap made cars of questionable worth, to say nothing of those that are absolutely bad. Fancy catalogs and extravagant advertising, attractive as they may be, are no longer convincing. The speed clown has ceased to be a stellar attraction in the great automobile circus. We are all getting back to earth, settling down to the legitimate, and, like all lines that have gone before our time, it is the survival of the fittest.

PREDICTS HORSES WILL BE RARITY IN 1915.

By ASA PAINE,

PRESIDENT FLORIDA EAST COAST AUTOMOBILE ASSOCIATION.

American brains and machinery are successfully producing many very superior automobiles which are suitably adapted to the road conditions of this country. Foreign makes of automobiles are being driven from our markets by equally as good machines at much less cost, made by many very reliable concerns. We now have a surprising array of reasonably priced cars, most of them substantial and well worth the prices asked. I want the pleasure and satisfaction of seeing my prediction come true—that by 1915 horse-drawn vehicles of all kinds will be a decided rarity, at least on the congested thoroughfares of large cities. Racing under proper conditions is of great importance in the complete development of a strong, safe, and good motor car, and should be encouraged by manufacturers. I believe the good roads problem is being rapidly solved and that an automobile of some kind will soon be a universal necessity in every well-regulated family.

FORECASTS AND CALCULATIONS INADEQUATE.

By PETER L. STEENSTRUP,

SECRETARY AND SALES MANAGER HYATT ROLLER BEARING COMPANY.

Words are really lacking in the staid old English language to express the stupendous, marvelous and gigantic development of this young but overgrown industry. The effect that the automobile has had on our business is reflected in the majority of other cases and tells the story possibly plainer than any thing else. As manufacturers of an anti-friction bearing for a large variety of purposes, the use of this bearing for auto-

mobiles was four or five years ago a mere incident in our general business. During the past years we have found ourselves constantly short of facilities, although each year we have erected such additional buildings as seemed more than ample to even the most sanguine expectations, so far as the increase of business is concerned. We have, in common with hundreds of other manufacturers, found ourselves in the unique position of being unable to sufficiently provide for the increase of such business as is practically forced upon us because of our inability to obtain in the market delivery of machine tools in less than from eight to fourteen months—machine tools which a few years ago could have been picked up in stock in any big city.

The growth of the automobile industry, which two years ago was predicted as approaching its zenith, throws all forecasts and calculations to the winds. The industry to-day is scoring a "beat" on all other industrial developments within the memory of man, and the ultimate outcome is completely hidden in a seemingly endless and accelerating demand for cars.

NOTHING BUT A PANIC CAN STAY PROGRESS.

By EZRA E. KIRK,

GENERAL SALES MANAGER B. R. THOMAS MOTOR COMPANY.

I regard the automobile business as the most wonderful development of an industry that this or any other country has ever witnessed. I have given more or less thought to the business, and have tried to look at it from various points of view. I have not the reputation of a pessimist, and certainly try not to be an extreme optimist. Looking at the situation from various points does not disclose a cloud on the horizon. The decided improvement in the quality of the production argues for the continued prosperity of the business as a whole. In my opinion, the only condition that could bring about a change in the present conditions that surround the automobile business would be a decided panic, and even this condition would not prove as serious as it would have in years gone by. The greatest danger to the industry is that of over-production. I believe, however, that the manufacturers have discounted this danger, and are proceeding along cautious and consistent lines.

As my efforts have been confined entirely to the building and merchandising of pleasure vehicles, I do not regard myself competent to even venture an opinion on the commercial wagon. From the point of view of an outsider, however, I should say that the successful commercial wagon was in sight; in fact, had arrived, and that very little further development is required to warrant its production in quantities. I believe that the volume of production of commercial wagons would so far exceed that of pleasure vehicles that comparisons will hardly be possible.

UNCERTAIN STAGE OF INDUSTRY HAS PASSED.

By GEORGE M. DICKINSON,

NATIONAL MOTOR VEHICLE COMPANY.

We have never, in our automobile experience, felt as much encouraged over the prospects as we do at the present time. We have found a great demand for our product in all portions of the United States, and we understand that all makers of good cars are as busy as ourselves, and from all we have been able to learn these conditions will prevail for some time to come. The automobile business has passed that uncertain stage when the purchaser of a car felt he was buying a "pig in a bag," as it were, but he purchases a machine now from a reputable maker with perfect confidence, and we are quite sure there are a great many buying automobiles who in the past have felt that the business had not reached the proper stage of development to make it worth their while to purchase a machine. We look forward to a heavy demand for a car, such as we are making for some years to come, and are laying our plans accordingly.

MUCH GREATER THE FUTURE THAT AWAITS.

By ALEXANDER WINTON,

PRESIDENT WINTON MOTOR CARRIAGE COMPANY.

Great as the automobile industry now is, its future will be far greater. The manufacture and use of pleasure cars, which have demonstrated the practicability of the self-propelled road vehicle, is simply a primary step toward the manufacture of cars destined to do the world's trucking. Thus far American manufacturers have been so extremely busy manufacturing pleasure cars that the wider and richer field of commercial wagons remains to-day practically uninvaded. This condition is certain to be changed. The change may not come rapidly, and preferably it should not come with a rush, for the commercial vehicle proposition, presenting somewhat different aspects from the pleasure car proposition, is one to be handled with deliberation.

The demand now exists for power wagons capable of doing greater work at less expense than is possible with horse-drawn vehicles. In recognition of this demand our manufacturers are devoting themselves quietly, but none the less seriously, to the production of vehicles which shall be wholly successful from the instant of their introduction. It would be a vital error to market power wagons with undue haste, since the use of unsatisfactory wagons would prove an unwelcome advertisement and seriously retard progress. Established manufacturers appreciate this possibility and need no warning. The danger, to my mind, is threatened by the possible invasion of the power wagon industry by latent capital bent upon the quick production of big dividends.

MAKERS ARE TO BLAME FOR DELAYS.

By H. S. WHITE,

ASSISTANT GENERAL SALES MANAGER SHELBY STEEL TUBE COMPANY.

At the present time every automobile manufacturer of importance has all the work that he can take care of, and with continued prosperity throughout the country this condition should continue throughout the year of 1907. We realize that one serious handicap to the automobile manufacturer this season is the inability to secure as promptly as they may desire material which enters into the construction of their vehicles. This, however, is largely the fault of the manufacturers themselves, as it has been the custom in the past to defer placing orders for material until such a time as their engineering department had completed all of their experiments and plans.

For the good of the trade, it would be wise on the part of the manufacturer to complete his experiments far enough in advance so that there should be no difficulty whatever in placing specifications four to six months in advance of their actual requirements.

For our own particular product there has been an exceptional demand from all parts manufacturers and the completed vehicle manufacturers, and we feel convinced that the year of 1907 will be a very prosperous one for all connected with the industry.

USELESS WEIGHT MUST BE DISPENSED WITH.

By H. H. FRANKLIN,

PRESIDENT H. H. FRANKLIN MANUFACTURING COMPANY.

Up to date the automobile has not been the money maker expected. Only the leading makers and dealers have been able to show satisfactory profit. The buyer of the automobile has also been a loser. He has had to buy the experimental product and with the maker has shared the enormous cost of development. But here is the funny part of it—both buyer and maker have thought that with the appearance of a car that was reliable and so built as to stand several years' use, the expensive development and changing business would be at an end and both would settle down, the one to enjoy, the other to make, much profit. Not so! Along with the present reliability and lasting qualities is an element—a big trouble—that must be

overcome. It is useless weight. The buyer now knows that his heavy car must be replaced by a light one and the maker is already groaning because of the pending burden of new design and new methods of construction. So acute is buying sentiment that the heavy car maker recognizing it no longer gives weights, and is sore pressed if asked to do so.

A FUTURE THAT IS MOST PROMISING.

By W. C. MARMON,
PRESIDENT NORDYKE & MARMON COMPANY.

The future of this great business is most promising. The demand for pleasure vehicles will no doubt increase for some time to come, and in our opinion there will always be a large demand for practical vehicles. While great improvements in construction are going on there is a noticeable change for the better taking place in business methods, and there is a gradual working out of the whole proposition towards a sane and substantial business basis which is most encouraging.

The commercial vehicle proposition, which has come to the front rapidly, will soon be another strong factor in making the business a flourishing industry for many years to come. We do not pretend to supply the demand for our cars and we presume that nearly all other manufacturers are in the same boat. There is bound to be an end to this condition, however, though there is probably room for more manufacturers just now. Latter on a weeding out may be expected and the proposition will resolve itself into one of the "survival of the fittest."

IT IS SERVICE, NOT FASHION, THAT COUNTS.

By THOMAS HENDERSON,
VICE-PRESIDENT WINTON MOTOR CARRIAGE COMPANY.

In careless speech the popularity of the automobile is sometimes referred to as a "fad." To that expression I object. A fad is defined as a passing fancy or a capricious hobby, and neither phrase is accurate insofar as the motor car is concerned. To be sure, Mrs. Jones may insist upon her husband buying an automobile because the Greens next door have one, but I know from experience that the Jones family will continue the use of their car even should the Greens cease to be factors in the neighborhood social life. And that is because the motor car performs a service which its owner finds he cannot get along without. Indeed, once he realizes how much more largely the motor car contributes to his enjoyment of life, he lastingly regrets his delay in purchasing. And it is wholly upon this single item of service that the whole future of the motor car rests secure.

DENVER AS AN AUTOMOBILE CENTER.

DENVER, COL., Jan. 14.—It is doubtful if another city in the country of equal size can equal Denver's record for 1906 automobile buying. There are seventeen agents in the city, who together represent forty-five different makes of motor cars, and the agents sold to Denver people a total of 560 cars of an aggregate value of \$1,065,500, or an average value approximately of \$1,900 each. In addition to selling to Denverites 560 cars, the local agents sold 175 to customers residing in various parts of the State. These cars had a value of \$332,450, or an average value of \$1,900. Thirteen more cars valued at \$47,600 were purchased by persons living in States west and north of Colorado.

The grand total of the automobile business in the matter of 1906 models and from the few 1907 models shows that 7.8 cars, valued at \$1,445,500, were sold in Denver last year; add to this approximately \$100,000 paid for second-hand cars and the revenue in this one particular industry goes beyond the million and a half mark.

Denver did not buy cheaply, the greater number sold being touring cars. Local pride says this indicates that Denver wants only the best.

BOOKS ON AUTOMOBILING.

Winged Wheels in France.

In a handsomely illustrated volume just published by G. P. Putnam's Sons, Michael Myers Shoemaker, tells of his run through the sunny land of France. The winged wheels were those of a 24-horsepower automobile, which confined itself to the modest speed of forty-five miles an hour, leaving faster progress to the 90-horsepower machines, which rushed past as though the author's car was standing still. Here are glimpses of stately old chateaus, some in ruins, some still inhabited, and made rich by tapestries which have hung there for centuries; information about roads and hotels; tempting bills of fare; sage warnings of discomforts to be shunned; types of national character; sketches of persons and events associated with the scenes described. The old walled town of Carcassonne was one of the traveler's few disappointments.

The descriptions are graphic, and there is a wise avoidance of the geographical details which often incumber books of travel, giving them the tone and aspect of guide books. The long tour was unmarred by any serious mishaps, although the number of French dogs was somewhat decreased. The book is illustrated by about sixty reproductions of photographs, and has a good index.

From the Rubber Tree to the Automobile.

"Rubber Tires and All About Them" is the title of a volume by Henry C. Pearson, editor of the *India Rubber World*, which deals with the rubber tire of every kind, and from every possible point of view. Beginning with the crude rubber in the South American forest, the material is followed through the various stages of manufacture until it emerges a complete tire. The theory, as well as the history of the pneumatic tire are gone into at length and present-day methods of construction are described. The book is profusely illustrated throughout, and as Mr. Pearson is an authority on the subject his work should be of value to those seeking tire information.

ITALY'S AUTO EXPOSITION AT TURIN.

U. S. Consul A. H. Michelson advises that the Automobile Club of Turin will inaugurate its fourth annual international automobile exposition in the newly enlarged Palazzo delle Belle Arti of the Valentino on February 16, 1907. Turin is Italy's greatest automobile center.

The exposition is under the patronage of the King of Italy, and will this year assume proportions not heretofore attained. Turin is the most important automobile center of Italy, and probably of Europe. It contains 21 of the 51 Italian companies engaged in the construction of automobiles, 6 of the 19 Italian automobile coach-builders, and 7 of the 30 Italian makers of automobile accessories; a total of 34 out of the 100 Italian companies that manufacture automobiles and their accessories. In the exposition of last year there were 102 exhibitors, only two of which showed American cars. Thirty thousand paying visitors saw the exposition.

It is most important that a good number of American makers be represented in an exposition held in such a center of the automobile trade as Turin. While for high-power touring cars American makers will find the competition of European firms exceedingly difficult to meet, this should not prove the case with cars lower in horsepower and price. The exhibiting of lightweight runabouts should prove especially worth while. So far the Italian makers have failed signally to realize the possibilities of good cars of this description on the Italian market. It can safely be said that American initiative which places runabouts and other lightweight cars upon the Italian market at a price not over \$1,000 will be attended with success. Cars of this description should have as long a wheelbase as possible, should be fitted, not with one, but with two or more cylinders, and should be driven by magnetic ignition.

LETTERS INTERESTING AND INSTRUCTIVE

MORE ABOUT TWO-CYCLE PISTON INLET VALVES.

Editor THE AUTOMOBILE:

[534.]—Having made innumerable experiments with the inlet valve in the piston—in fact, I have devoted nearly all my time to this type of motor—I wish to call your attention to an error in Mr. Malcolm's idea as published in your issue of the 27th. The position of the valve is exactly the reverse of what it should be, and it would be impossible to operate a motor with a valve in this position, as the first explosion would dislocate it, to say nothing of what the heat would do to the spring. I presume Mr. Malcolm got this idea from a description of one of my engines, sent by me under the name of Carter to C. E. Duryea, of the "Cycle and Automobile Trade Journal," for criticism about a year ago.

FIG. 1.—Sectional view of two-cycle engine with horizontal valve in piston suggested by C. E. Duryea about a year ago.

In my first engine I used the crankcase compression, but soon found this unsatisfactory in many ways, and turned my attention to other means of compression. Two methods appeared the most practical, namely, the separate compression cylinder and the double-ended power cylinder using the stuffing box end for compression. I chose the latter construction as it would, in my mind, make the most simple engine. This construction, of course, requires the use of a crosshead, but I think this preferable to the separate compressing cylinder, as it is much more compact, and will give a better balanced engine, a very important feature. The stuffing-box on this engine works under a light pressure, and is always cool and easily lubricated, and will run for months without attention or leaking. The crosshead can be made very light with ample wearing surface. Those used in my engine are made of steel, honeycombed and case-hardened. The adjustments for wear are made on the slides instead of on the crosshead, and as the strain is on one side of crosshead on the down stroke and on the opposite side on the up stroke, the wear is very even. I next turned my attention to producing a variable compression motor, as I found a high compression undesirable for slow speeds, while it gave the best results for high speeds, and vice versa.

Now the ideal condition is to have just enough compression to transfer the given amount of gas at each stroke at any speed, and this certainly cannot be accomplished with a fixed compression. To get this result I built my engine on the principle shown in Fig. 2. The piston A is closed at its lower end; an automatic poppet valve located at B opens into the hollow piston; the automatic valve at C opens into the combustion chamber K and F; the gas is admitted to the lower end of cylinder through the rotary valve D on the up stroke of piston; an automatic poppet valve operates very satisfactorily in place of the rotary valve and requires no gearing.

On the down stroke of the piston the gas is transferred through valve B into the piston chamber, the explosion of the previous charge holding valve C on its seat. Now it will be clearly seen that on each up stroke of the piston a charge of gas equal to the piston displacement minus that of the rod, which is slight, will be taken into the lower end of cylinder. On the down stroke this

entire charge of gas will enter the piston because the said piston comes within 1-16 to 1-32 of an inch of the lower end of cylinder. This charge, of course, having no effect whatever on the next, as the valve B closes the instant the piston starts on the up stroke, confining this gas in the piston. Consequently, on each down stroke a charge of gas, practically equal to the piston displacement, will be delivered to the piston regardless of the speed at which the engine is running when throttle is wide open. When the engine is running the action is as follows: As soon as the piston approaches the lower center, the ports EE are uncovered and the burned gases escape through these, as in an ordinary engine. As soon as the pressure in the cylinder falls below that in the piston the valve C is thrown open by the compressed gas in piston, which rushes into the cylinder, first clearing chamber K of burned gases, then rising in a column at the center of the cylinder.

The normal compression, or the compression on one down stroke of the piston, is about six pounds when throttle is wide open. This compression is sufficient to transfer the full charge at low speeds only. As soon as the engine is speeded up so fast that six pounds is not sufficient to transfer the full charge to the cylinder, the part not transferred will be left in the piston under a slight pressure, this pressure, as before stated, having no effect on the next charge.

Now, for convenience, we will suppose the amount of gas or pressure left in the piston to be one pound. On the next down stroke of the piston the normal amount of gas or pressure, six pounds, is forced into the piston in addition to the one pound left from the previous charge, making the compression seven pounds, instead of six. If this is still too low to transfer the full charge, a part of this charge (we will say one pound) in addition to the previous one pound, will be left in the piston, raising the compression to eight pounds on the next down stroke of the piston. This action will continue until a sufficiently high compression is reached to transfer a charge to the combustion chamber equal to that taken in at the lower end of cylinder when the engine is being brought from a low to high speed. When slowing up, a slight overcharge will be admitted at each stroke until the engine reaches a fixed speed.

It will be noticed that the shape of the piston makes the ideal deflector, keeping the incoming gas in a column at the center of the cylinder when running on a full charge. When throttled down low, all the fresh gas remains in the piston chamber K. With the spark plug at center of cylinder head, the spark always occurs in a body of fresh gas, allowing this engine to be throttled exceptionally slow without missing.

By passing the gas through the lower end of cylinder and also through the piston it is brought to a much higher temperature than usual before entering the cylinder, thereby producing a thoroughly vaporized mixture, and at the same time keeping the piston and lower part of cylinder fairly cool. The exhaust ports extend entirely around the cylinder, and with this practice it is possible to make them much narrower, and at the same time get a greater area than with the ordinary practice. The narrow ports, of course, add to the power stroke. Again, by having the ports entirely around the cylinder, the expansion of same is very even, having no tendency toward distortion, as in a two or three-port engine, where the exhaust highly heats one side, while the other side is kept fairly cool by the incoming gas.

In my engine I use a crosshead and connecting rod similar to one used in a steam engine. By using a crosshead to take the side thrust, it is possible to use a much shorter connecting rod than usual without any bad results. The unusually short connecting rod also gives a considerably longer time than usual between the opening and closing of the exhaust ports. An excellent feature of this engine is that the

FIG. 2.—Sectional view of F. R. Wottring's two-cycle variable compression engine. This sketch is not drawn to scale.

charge is taken into the cylinder during the full up-stroke of the piston, allowing the use of any carbureter, this action being far superior to the short, quick rush of the three-port engine. The construction of this engine also admits of a perfect system of lubrication, which is by no means a small matter.

The crank bearings and pins, the slides and crosshead pin can all be liberally flooded with oil by the splash system without danger of flooding the cylinder. This oil also stays in a good condition, as it is not carbonized or burned in the cylinder. The cylinder can then be fed independently just the proper amount of oil to give the best results from a force or sight feed oiler.

Mr. Malcolm criticises the use of poppet or check valves in this motor. I would like to know if he considers the four-cycle engine a failure with its two and quite often three valves. Now, if a two-cycle engine will deliver two impulses to one of the four-cycle, and each one of them as good, or practically so, as the one, what would be the objection to the same number of valves in the two-cycle as in the four? In my engine only one valve is mechanically operated, and that is a rotary valve of the simplest form running at half the crankshaft speed. This valve works under a light pressure only, and at all times is cool, permitting of thorough lubrication, doing away with any danger of undue wear.

The valve B is simply a flat disk with a small, short stem, this valve being held in place by a light bridge H. It requires no spring, as the motion of the piston opens and closes it at exactly the right time. Valve C is a flat disk held in place by the nut L on an extension of the piston rod. The pressure of the gas in the piston opens this valve and the motion of the piston closes it. This fact that this engine will receive a slightly less charge of gas than the piston displacement, will cause some criticism, but the almost innumerable other good points more than make up for this one, by no means bad, feature.

The best three-port engine in the country will take in but very little over a charge of gas equal to one-half the piston displacement at high speed, while some take in less than this amount at slow speed, while at no time will any two or three-port engine take a charge of gas at every stroke, equal to the piston displacement.

L. R. WOTTRING.

Prospect, Ohio.

[**EDITOR'S NOTE.**—The error referred to by Mr. Wottring in the opening paragraph of his letter was one for which the draughtsman was entirely responsible, misplacing the valve in question in preparing the rough outline sketch, which was merely intended to illustrate the principle referred to in the accompanying text. We cannot say where Mr. Malcolm obtained his idea on the subject, but in presenting it he did so merely by way of review of proposed types of two-cycle engines, together with his views on their merits, and not by any means as an original conception of his own.]

POWER IN AIR- AND WATER-COOLED MOTORS.

Editor THE AUTOMOBILE:

[535.]—As a regular reader of your valued magazine, I write to ask if you will kindly give authoritative opinion and reasons therefor on the following statement: "A" affirms that with two motors of equal dimensions in every detail, same compression, etc., the motor with air-cooling system will develop more horsepower than the one water-cooled; for instance, the air-cooled motor will develop 30 horsepower, where the water-cooled motor can only develop 20 or 25 horsepower. "B" says such is not the case; that is, it is not yet practical.

S. BARRETT.

Carterst, N. J.

Theoretically speaking, of two motors alike in every detail of design and operation, the air-cooled motor should develop a greater amount of power than the water-cooled, but that the difference between the two would ever be so great as you mention is extremely doubtful. The reason for this is due to the fact that the efficiency of an internal combustion motor is measured by the number of calories or heat units in a given quantity of fuel that it converts into useful work. Generally speaking, water-cooling is over-efficient; it tends to keep the cylinder walls at a temperature below that at which the highest percentage of thermal efficiency is reached by the motor when in operation. There is naturally a limit to the temperature at which a motor can be run constantly under ordinary conditions, as the lubricant will vaporize or burn and the piston bind. The majority of makers prefer not to approach this danger line too closely; hence, the great heat losses in the water jacket. Air-cooling, on the other hand, may also be over-efficient, though this is not as likely

to be the case as with a water-cooled motor, and in consequence a greater percentage of the heat is apt to be utilized. But in the contention which your letter reveals, B is correct in stating that the construction of an air-cooled motor of the same compression and same mechanical details as a water-cooled motor of the same size has not been found practical. With the exception of motors of very small size, such as employed on the motor bicycle, it is not usual to design air-cooled motors with anything like the same degree of compression as is used in water-cooled motors of the same dimensions, owing to the extremely rapid rise of temperature with the compression. At first sight there appears to be no reason why this should not be done, but practice has shown otherwise. It is but one of the many instances in which theory and practice do not agree.

MORE ABOUT CRANKCASE BREATHERS.

Editor THE AUTOMOBILE:

[536.]—Permit me to correct a statement made by you in reply to letter from Wm. F. Long, in "The Automobile" of December 13, on the subject, "Use of Breathers on Crankcases." While expansion of air in crankcase, due to heat generated in running, as well as leaks of gas past the piston during compression and explosion periods are a proper *raison d'être* for breathers, your statement explaining other causes for unstable equilibrium are incorrect, as you will at once note. You state in answer to Mr. Long that "it is not a fact that downwardly moving pistons in a multi-cylinder engine exactly compensate for the upwardly moving ones—because the angularity of the connecting rod causes the pistons in upper half of strokes to move materially faster than in traversing the lower half." It is in this statement that you are wrong, which can be shown by more than one line of reasoning, as I will proceed to show.

1. Angular velocity of crank on the crank circle is same at all parts of a revolution for any given constant speed.

2. Piston travel (one way full stroke) is equal to diameter of crank circle.

3. Distance traveled (in one way full stroke) by piston is therefore equal to an angular motion of crank of 180 degrees, which is to express point 2 in other language.

4. The projection of that angle (180 degrees) upon the diameter. (Vertical diameter on a vertical engine and horizontal diameter on a horizontal engine.)

5. For any portion of the travel of crank and piston, therefore, the lineal measure of piston travel equals the projection of the crank circle arc of angular travel of crank upon the diameter of crank circle which coincides with center line of cylinder.

6. Projections at the top and bottom of strokes are therefore a minimum, and at middle of stroke are a maximum for any given angle of travel of crank on crank circle. This will be seen at a glance by projecting upon the vertical diameter (as explained above) the arc of angular travel of crankpin for the first and second—45 degrees of motion. This projection of first 45 degrees is less than one-half of the similar projection of the second 45 degrees. It would be easy to go into figures and prove this by trigonometry or to plot it and show it graphically, but it is hardly worth while.

For a more popular explanation it will be noticed that as piston changes its direction at end of each half stroke or cycle it must come to a stop and its velocity is therefore zero, whereas in middle of stroke its velocity is maximum. It is this very fact among others that makes all oscillating engines of steam and gas engine type of necessity slower speed motors than turbine and electric motors of rotary type. You were right in your idea that piston had a variable velocity, but wrong in your explanations and conclusions, for, as shown, the variation here is symmetrical and for all engines of even numbers of cylinders set 180 degrees apart the equilibrium is maintained, provided, of course, no two adjacent cylinders not 180 degrees apart are confined in a crankcase section, not connected so as to admit of free circulation or oscillation of the air confined.

This is all I sought to explain to readers of your extremely interesting and valuable paper. Still, we have to have the breathers for other reasons given by you.

J. FRANCIS BOOREAM.

Greenwich, Conn.

OHIO CITY WANTS FIRE APPARATUS.

Editor THE AUTOMOBILE:

[537.]—We are in the market for an automobile piece of fire apparatus, namely, a combination chemical engine and a hose wagon, machine to be arranged to carry one chemical tank, capacity 35 gallons, and 1,000 feet of fire hose. We would be pleased to hear from automobile builders as to what they have to offer.

Alliance, O.

WM. AUNGST, Chief, Fire Department.

FRANCE LEADS THE WORLD IN PROLONGED SPEED

In the three great long-distance road races of last year France captured all first place honors, but each time with a different driver. Szisz, with a Renault, won the Grand Prix; Duray, a Dietrich driver, succeeded in the Ardennes Circuit; and Wagner and his Darracq appropriated the Vanderbilt Cup. A feature of the 1906 racing was the use of dismountable rims, by which a saving of fifteen minutes was effected in changing tires. Owing to their widely differing lengths and road conditions, it is not possible to put the three international speed tests on a common basis. The Ardennes and Grand Prix circuits were about equally speedy, but the length of the former was only half that of the latter, and it is therefore not surprising that the highest average was obtained in Belgium. Compared with the two European courses the Long Island circuit left much to be desired for speed, yet its average is only slightly lower, as will be seen from the following table:

Ardennes Circuit: Duray; Dietrich; 372 miles, average 66 m.p.h.
Grand Prix: Szisz; Renault; 769 miles, average 63 m.p.h.
Vanderbilt Cup: Wagner; Darracq; 297 miles, average 61½ m.p.h.

The fastest rounds in each of the three contests were:

Grand Prix: Baras, Brasler, 74 miles per hour.
Ardennes Circuit: Wagner, Darracq, 70 miles per hour.
Vanderbilt: Tracy, Locomobile, 67.66 miles per hour.

Of world-famed drivers four competed in the three great road races, namely: Duray, Clement, Wagner and Jenatzy. Lancia did not run in the Ardennes, and Szisz confined himself to the

Grand Prix. Duray heads the list, comparing with his companions, as follows:

Duray—8, Grand Prix; 3, Vanderbilt; 1, Ardennes.
A. Clément—3, Grand Prix; 4, Vanderbilt; 6, Ardennes.
Jenatzy—10, Grand Prix; 5, Vanderbilt; 10, Ardennes.
Wagner—0, Grand Prix; 1, Vanderbilt; 8, Ardennes.
Lancia—5, Grand Prix; 2, Vanderbilt.
Szisz—1, Grand Prix.

Burton replaced Jenatzy in the latter half of Grand Prix; Wagner completed only two rounds.

The fastest short burst of speed in 1906—or in any year, for 1906 saw the breaking of all records—was given by an American-built machine, the Stanley steamer, driven by Fred Marriott. On the Ormond-Daytona beach he covered the mile on a flying start in :28 1-5, or at the terrific rate of 127.66 miles an hour. Although America occupies top position, France has a no less glorious record, and indeed over a two-mile stretch, with a flying start, left the American "Teakettle" behind, Demogeot with eighty-cylinder 200-horsepower Darracq clocking at :58 4-5, equal to 122.44 miles an hour, against his rival's :59 3-5, or 120.8 miles an hour. All the world's short-distance records, except the flying kilometer and flying mile, are held by the eight-cylinder Darracq monster, which, piloted by Hemery for the first time on the measured kilometer in the south of France at the end of 1905, then by Demogeot at the Florida meet, and latterly by the young English sportsman, A. Lee Guinness, has been everywhere victorious.

Distance.	Time.	Start.	Car.	Driver.	Place.	Rate of Speed.
1 mile	28 1-5 s.	Flying	Stanley steamer	Marriott	Florida	127.66
2 miles	58 4-5 s.	Flying	Darracq, 200-h.p.	Demogeot	Florida	122.44
2 miles	59 3-5 s.	Flying	Stanley steamer	Marriott	Florida	120.8
1 kil.	18 2-5 s.	Flying	Stanley steamer	Marriott	Florida	121.57
1 kil.	19 s.	Flying	Darracq, 200-h.p.	Guinness	Ostend	117.6
1 kil.	26 2-5 s.	Flying	Darracq, 80-h.p. light racer	Walker	Ostend	84.6
1 mile	45 2-5 s.	Standing	Darracq, 200-h.p.	Guinness	Ostend	79.2
100 miles	1:15:40 2-5		Napier	Earp	Florida	79.2
1 kil.	29 s.	Flying	Darracq, light	Demogeot	Gallion Hill	77.0
100 kil.	52:49		Darracq	Wagner	Ardennes Cir.	68.6
1 kil.	33 2-5 s.	Standing	Darracq, 200-h.p.	Guinness	Scheveningen	66.9
1 kil.	40 1-5 s.	Standing	Darracq, light	Walker	Scheveningen	55.6

GRAND PRIX RACE NOW CERTAIN:

PARIS, Jan. 10.—The fears of the Sporting Committee of the A. C. F. and of all French constructors interested in racing, have been allayed by the official announcement by M. Clemenceau, that permission for the holding of a long-distance road race will not be refused. Owing to semi-official reports that the government intended to put a ban on road racing, a deputation recently waited upon the Premier and asked for an official declaration. A circuit will now be selected, permission obtained from all the interested local authorities for the monopolizing of the roads, and a further request for authorization made to the head of the government—all a matter of formality. Proposed circuits are numerous, every district having a good set of roads doing its best to obtain the favor of the A. C. F. Fontainebleau circuit, near Paris, is the only one that has been officially examined, and is now found unsuitable. Auvergne and the Ardennes, both good racing grounds, are putting forth claims, but the financiers favor a course nearer Paris.

The first three entries for the Grand Prix have been made by the Bayard-Clément firm, the machines to be driven by Albert Clément, Pierre Garcet and Villemain. Three six-cylinder racers were built during the fall, two of them being now tried out on the road. It is very probable that these will be the machines selected for the Grand Prix. The Brasier firm, whose participation in road races next year was somewhat doubtful, has just announced that it will compete in all the principal events of 1907.

RECORD ENTRY FOR EMPEROR'S CUP.

PARIS, Jan. 8.—Seventy-four engagements have been received for the German Emperor's Cup, to be run on the Taunus circuit next June. This is the largest number of cars ever entered in a long-distance road race since the ill-starred Paris-Madrid test. Entrance fees for cars alone reach a grand total of \$55,500, and this will be further increased by the rental of tire and gasoline stations on the course. Of the seventy-four machines, 32 are German, 18 French, 12 Italian, 3 English, and the remainder Swiss and Belgian. Well-known drivers who will figure in the race include Lancia, Nazzaro and Weillschot for Fiat; Wagner, Hanriot and Demogeot for Darracq; Jenatzy for Mercedes, and Duray, Rougier and Gabriel for De Dietrich.

A certain number of important French constructors, amongst them Renault, Panhard, Braiser, Hotchkiss and Bayard-Clément, have withheld from the race on the ground that the regulation limiting cylinder volume was not such as would improve the construction of automobiles. The race will be run on a 52-mile course, thus it is certain that the first car will be round to the starting line while machines are waiting to start.

DEMOGEOT ENTERS THE MARRIED RANKS.

PARIS, Jan. 8.—Victor Demogeot, the Florida speed king, has just "buried his bachelor days"—as the French put it. The ceremony took place in the frontier town of Nancy, the bride being Mlle. Marie Cardot, a charming young lady of that city.

THE PATHFINDING "ALLIGATOR" ATTRACTED ATTENTION ALONG THE ROUTE. THIS PICTURE IN WINNSBORO, S. C., BEING TYPICAL.

FROM THE BIG TOWN TO ORMOND'S SANDS

WHEN Ralph Owen left Columbus Circle, New York, Sunday, Dec. 23, he predicted that he would pilot the Oldsmobile to the Ormond-Daytona beach in twenty days. As events turn out, he has had not only made good his prediction, but with the liberal margin of two days to spare. The Oldsmobile "Alligator," after making the run from St. Augustine to Ormond in the record-breaking time of four hours, despite the difficulties encountered, and after having duly accepted the hospitality of the eight carloads of enthusiasts who met the path-finding party where the road emerges from the almost impassable swamps to the beach, covered the eight miles to the clubhouse of the Florida East Coast Automobile Association, at Daytona, with things running better than the day of the departure from New York, arriving there Saturday afternoon.

Ever since the Oldsmobile party has crossed the border line between Georgia and Florida, its progress through the latter State has been more akin to a triumphal procession than a tour of exploration through a country not graced with anything that can be deservedly given the title of roads, except in short stretches.

The trip from the Georgia line to Jacksonville was characterized by a plunge through the Altamaha Swamps, during the passage of which the car was up to its hubs in mire and water for a large part of the time. The only washing that the car has received, or rather the most complete wash, for the entire trip has been but a succession of alternate mud and water baths, has been received in crossing the unusually deep fords in these southern streams.

Despite the deep sand and frightful holes caused by recent unusually heavy washouts which have undermined the roads in numerous places, a quick trip was made to Jacksonville, where the party was really treated to an ovation, due to the enthusiasm with which the southern press generally has greeted the idea of road improvement. Their coming was looked forward to and as soon as they arrived a self-appointed committee of prominent automobilists undertook to give them a reception as long as

they cared to stay. They were shown the sights of the town. The party finally left Jacksonville bound for St. Augustine to the strains of "Dixie," rendered by the local brass band assembled on the sidewalk in front of the hotel to do them honor and speed the parting guests with best wishes for the successful

IN A SOUTHERN GEORGIA COTTON FIELD.

outcome of the trip, for while the stretch from Jacksonville to Ormond was not at all feared, as the roads are fairly good throughout that section, it was thought that the comparatively short span from St. Augustine to Ormond would prove one of the worst parts of the trip, if not altogether insurmountable. The expectations of the party were not disappointed with regard to the good traveling to be found between Jacksonville and St. Augustine, and they rolled along at a good pace over the shell road that joins the two cities. On several occasions, however, it looked as if hours would be lost in getting around some of the heavy washouts that had occurred as the result of recent bad storms. Whenever one of these large crevasses in the road was met with there was no alternative but to look for an opening in the trees sufficiently wide to admit driving the car through in order to find a way around, or, if that was not possible, to attempt to strike some parallel road.

Upon arriving a few miles from the outskirts of St. Augustine, which does not cover a great deal of ground, the party was met by a reception committee, who had come out some distance in several cars to meet them. Not long after leaving St. Augustine, the party was met by a car which had come up to escort them on the last lap of the trip. Though the going was far from favorable, it was nothing like as bad as had been anticipated on this part of the journey. None of the southern States below the Virginia line can boast of much in the way of roads, but when it comes to traversing the Florida swamp country it is difficult to find anything to make comparison with.

It was with a great sigh of relief from every member of the party who had been battling with road difficulties, such as only those who have attempted to explore the backwoods country of the South are familiar with, that they suddenly came to a place where the miserable thicket road opened out onto the beach and their pleasure at making the discovery that this marked the end of their troubles. Eight carloads of enthusiasts were awaiting them at this point, and amid much cheering and congratulations the whole fleet of cars raced down the smooth beach toward the hotel at Ormond, where a stop was made for congratulations of a more substantial order. From this point only eight miles of as good running as ever an automobile was raced over lay between them and the finale of their long journey, and after the congratulations and "have another" had

PLOUGHING ITS WAY THROUGH A SOUTHERN GEORGIA SWAMP.

come to an end, they were given three rousing cheers to speed them on the last few minutes' run to Daytona.

The total time consumed in making the trip was twenty days, of which two days were spent in celebrating Christmas, the car being left at Harrisburg, Pa., in the meantime, so that the running time was but eighteen days, or two days less than Mr. Owen predicted was necessary to make the trip.

THERE WERE STRETCHES OF PICTURESQUE ROAD, SOMEWHAT SANDY BUT FAIR GOING, IN SOUTH CAROLINA.

A RUN IN SUNNY SOUTHLAND.

CHARLESTON, S. C., Jan. 12.—They were twelve—cool, clean and respectable looking—when they lined up at the Commercial Club, in Charleston, at 10:38 o'clock on the morning of December 29. Three hours and ten minutes later they were eleven warm-blooded pulsating little machines, strong and vigorous under their layer of brown mud, outside the Pine Forest Inn at Summerville. It was new to most of the people who took part in this first demonstration in force that was ever made on the "dirt" roads of South Carolina—in "these diggin's," as a local newspaper expressed it, reporting the run. Some of the party sat still and held on; one man lay down and established a close acquaintance with gentle mother earth while vainly endeavoring to repair a chain and broken springs, which gave out on one of the rough parts of the road. All had experiences of a more or less exciting nature, and everybody got back home by early candle lighting, as the saying used to be in the up-country before the strenuous age began.

The route chosen was a picturesque one. Leaving Charleston the way lay across the Ashley River and along the Ashley River road, passing the well-known Magnolia Gardens, Drayton Hall and many other plantations that in days gone by were famed for their beauty and the liberal hospitality of their owners. The route was divided into ten controls, and Morton B. Paine,

IN FRONT OF PINE FOREST INN, SUMMERVILLE.

One of the results of the tour will be the inauguration of a movement for the construction of a fine boulevard from Charleston to Summerville. Pine Forest Inn is one of the noted Southern resorts and ought to be easy of access by automobile. If it can be made so by the Charleston's automobilists it will be.

The cars participating in the run and their drivers were as follows: Official car, 20-horsepower Reo, M. B. Paine, Jr., tour manager; driver, N. H. Blicht; 20-horsepower Premier, F. G. Davies; 20-horsepower Reo, T. B. Jenkins; 20-horsepower Reo, C. M. Gibson; 20-horsepower Reo, E. A. Jenkins; 20-horsepower Reo, J. E. Richards; 20-horsepower Cadillac, Eugene W. Smith; 8-horsepower Reo, N. H. Blicht, Jr.; 8-horsepower Reo, M. B. Blicht; 8-horsepower Reo, H. E. Richard; 8-horsepower Reo, J. W. Martens; 8-horsepower Reo, J. R. Barker; 10-horsepower Cadillac, J. H. Rast.

THE COMING ORMOND-DAYTONA MEET.

When the list was closed at 3 o'clock on Monday last for the races to be held on the Florida sands next week, it became known that more than 100 entries were assured for the meet. Prominent among the high-powered racing cars nominated are the 100-horsepower Darracq to be driven by Wagner; S. B. Stevens' 80-horsepower car of the same make; J. R. Harding's 90-horsepower Mercedes; H. W. Harroun's eight-cylinder 500-pound Harroun; Fred Marriott's 30-horsepower Stanley steamer, and H. E. Rogers' long distance Stanley. The stock events have attracted a great many more entries than were expected, the Stevens-Duryea, Winton, Peerless, American, Wayne, Welch, Elmore, and Stanley steamers being well represented. The manner in which steam has carried everything before it at the kilometer and mile being so well-known, the outcome of the entry of a steamer for the long distances is looked to with considerable interest.

LOVELY RIDGEWOOD AVENUE IN PICTURESQUE DAYTONA.

THE STOP AT THE FIRST CONTROL NEAR CHARLESTON.

Jr., who headed the line in his 20-horsepower Reo official car, distributed the confetti which identified the way. In several places along the route there were stretches of water covering the roadway, four to six inches deep, which in turn would be succeeded by hills, the worst one of which was encountered just before reaching Middleton's Gardens, 17 1-2 miles from Charleston. This hill has a rise of 72 feet in 300, and was a wet, slippery mass of clay. When the pineland was reached a few miles out from Summerville road conditions improved.

At the Pine Forest Inn, Summerville, a delightful dinner was served to the hungry tourists by the host, Captain F. W. Wagener. Plans were discussed among the participating autoists for the formation of the Charleston Automobile Club—the consummation of which is a matter of the near future—and with true Southern spirit, J. H. Rast, who drove a 10-horsepower Cadillac, and E. A. Jenkins, who piloted an 8-horsepower Reo, agreed to test out respective merits of their cars by a race on the homeward bound trip. The official car and two others left in advance of the rest to reach Charleston in time to judge the race at the finish. It was an exciting run, and the participants only slowed down when humanity demanded it, but they slackened not when the slush reached their axles, and when curves were met they took them as Hemery showed us how. The Cadillac got in first, but the Reo was only ten seconds behind. After the racers came the remainder of the party, and every car was accounted for shortly after dark.

THREE BILLS ALREADY AT ALBANY.

ALBANY, N. Y., Jan. 14.—There is a very evident attempt to get next to motor vehicle legislation by a number of statesmen of the lower branch of the Legislature. Assemblyman Cuvillier, of New York, has a bill to license all owners, lessees, and operators of automobiles or motor vehicles not propelled by horse power and allowed on public streets and roads, except railroads. The license fee is \$25. The bill also provides for chauffeurs of twenty-one years or over who shall pass an examination before getting a license to run a car. If anyone after getting a license shall run over anyone and kill or injure the same he shall have his license revoked and be guilty of a misdemeanor and subject to a year's imprisonment and a \$500 fine, or one or the other.

Assemblyman Northrup, of Dutchess, has an amendment to the present motor vehicle law of 1904 which provides that no person shall operate a motor vehicle on the public highways that is geared to run more than one mile in four minutes. The same bill provides for requiring the age of a chauffeur to be stated in the statement he or she makes when getting a badge from the Secretary of State, and provides that a chauffeur must be sixteen years old or more.

Assemblyman Stanley, of New York, introduces again that old bill of his of last year, which provides for a State commission of three and an expensive counsel and a big office staff, and power to regulate automobile affairs. The bill was opposed last year by the New York State Automobile Association.

AN AUTO BILL BY THE MISSOURI MEMBER.

WASHINGTON, D. C., Jan. 14.—Automobile manufacturers and those allied with the motor car industry will be affected by the enactment of a bill introduced in Congress by Representative DeArmond, of Missouri. The object of the bill is to provide for the marking of rates of tariff duty upon manufactured articles and to fix the punishment for the violation of the provisions thereof. The bill provides in effect that upon each and every article of domestic manufacture upon which, if of foreign production and imported into the United States, there would be levied a tariff or customs duty of 30 per centum or more, or a duty amounting to 30 per centum or more of the dutiable value thereof, there shall, before the same is taken from the place of manufacture, be marked, plainly and as indelibly as may be practicable, the rate of duty imposed by the law upon the like article when imported. Whoever shall sell or dispose of any such article not so marked or shall, prior to acquiring it for use by himself, family, or employees, remove, destroy or obliterate any such mark or marking, shall be guilty of a misdemeanor, and for each offense shall be punished by a fine of not more than \$5,000 or by imprisonment for not more than one year, or by both such fine and imprisonment; and all such articles not marked as aforesaid shall be forfeited to the United States.

This bill has been referred to the House Committee on Ways and Means. Its enactment into law would make it obligatory upon every automobile manufacturer to stamp his car the rate of duty now imposed upon foreign cars, 45 per centum ad valorem. It is hardly believed that the DeArmond bill will be taken seriously by Congress.

WASHINGTON STATE AFTER GOOD ROADS.

SEATTLE, WASH., Jan. 12.—In its general features the New York law for the building of roads has been adopted by the legislative committee of the Washington Good Roads Association. This law contemplates the distribution of the cost of building roads by the State paying 50 per cent., the county 35 and the local improvement district 15. The maintenance will be assumed by the State. It is estimated that there will be available in the road fund for 1907 the sum of \$132,000 and \$148,000 the following year. If the legislature passes the bill this winter it means that half a million dollars will be expended on roads in this State in the near future.

THE AUTOMOBILE CALENDAR.

AMERICAN.

Shows.

- Jan. 19-26.....—Baltimore, (Md.) Automobile Show of the Automobile Club of Maryland and Dealers' Association.
- Jan. 21-28.....—Los Angeles, Cal., Morley's Rink, First Automobile Show of the Automobile Dealers' Association of Southern California.
- Jan. 28-Feb. 2...—Washington (D. C.) Automobile Show, Dupont Garage, Washington Automobile Dealers' Association.
- Feb. 2-9.....—Chicago Automobile Show, Coliseum and First Regiment Armory. S. A. Miles, manager, 7 E. 42d Street, New York City.
- Feb. 11-16.....—Detroit, Mich., Sixth Annual Automobile Show, Light Guard Armory, Tri-State Automobile and Sporting Goods Association. E. E. McMasters, manager.
- Feb. 18-23.....—Fifth Annual Automobile Show, Buffalo, Convention Hall. D. H. Lewis, manager, Teck Building.
- Feb. 25-Mar. 2...—Portland, Me., Second Annual Automobile and Power Boat Show, The Auditorium.
- March 2-9.....—Chicago, Second Annual Power Boat Show, Seventh Regiment Armory. W. C. Andrews, manager, 19 E. Huron street.
- March 4-10.....—Kansas City, Mo., First Annual Automobile Show, Convention Hall. Frank L. Woodward, manager, Willis Wood Theatre Building.
- March 18-23.....—Providence (R. I.) Automobile and Power Boat Show, Infantry Hall. F. M. Prescott, manager.
- April 6-13.....—Montreal, Canada, Second International Automobile and Sportsman's Exhibition. R. M. Jaffray, manager, 309 W. Notre Dame street.
- April 8-13.....—Pittsburg, Pa., First Annual Show of the Pittsburg Automobile Dealers' Association, Duquesne Garden.

Race Meets, Hill Climbs, etc.

- Jan. 22-26.....—Ormond-Daytona (Florida) International Race Meet, Florida East Coast Automobile Association.

Motor Boat Races.

- Jan. 29-Feb. 1...—Palm Beach, Fla., Annual Races of the Palm Beach Power Boat Association.
- June 8.....—670-Mile Ocean Motor Boat Race, New York to Bermuda. Motor Boat Club of America and Royal Bermuda Yacht Club.
- Sept. 2-6.....—Jamestown (Va.) Exposition, Motor Boat Races.

FOREIGN.

Shows.

- Jan. 18-26.....—Birmingham (Eng.) Automobile Show.
- Jan. 25-Feb. 2...—Liverpool Motor Show, Tournament Hall.
- March 7-16.....—London, Olympia Commercial Vehicle and Motor Boat Show.
- April 6-13.....—London, Agricultural Hall Motor Show.
- May 1-15.....—Madrid, Spain, Automobile Exhibition, Palace of Fine Arts, Royal Automobile Club of Madrid.
- May 15-28.....—Third Annual Swiss Automobile and Cycle Show, Zurich.

Race Meets, Hill Climbs, etc.

- Feb. 23-27.....—Volturette Contest, Automobile Club of Italy.
- March 20-27.....—Nice (France) Automobile Week.
- April 1-15.....—Spring Wheel Competition.
- April 21.....—Targa Florio Tour (Slilly), Auto Club of Milan.
- April 25-28.....—Touring Contest, Automobile Club of Touraine.
- April 28.....—Chateau Thierry Hill Climb.
- May 1-15.....—Paris-Madrid Touring Competition.
- May 24-27.....—Volturette Contest, Automobile Club of Austria.
- May 29-June 1...—Irish Automobile Club Reliability Trials.
- June 3-12.....—Herkomer Cup, Automobile Club of Bavaria.
- June 14.....—German Emperor's Cup, Taunus Circuit, Imperial Automobile Club.
- June 24-29.....—Scottish Reliability Trial, Scottish Automobile Club.
- June 25-July 8...—Grand Prix, Automobile Club of France. (Exact date to be decided upon.)
- Aug. 11-20.....—Coupe d'Auvergne, France.
- Aug. 18-22.....—Ardennes Circuit (Belgium) and Coupe de Liedekerke.

WINTER DOINGS IN AUTOMOBILE CLUBDOM

President Caverly, of Washington Club, Energetic.

WASHINGTON, D. C., Jan. 14.—Robert B. Caverly, the newly-elected president of the Automobile Club of Washington, is losing no time in getting "on the job." In a circular letter to the members of the club he says, among other things: "It will be my pleasure to carry out the constitution and by-laws as adopted and to the best of my ability increase the pleasures and privileges of the members in the objects for which the club was originally organized. It will be impossible for any large amount of success to ensue without the hearty co-operation of every member, and to this end I avail myself of this opportunity to request each member to advise me fully as to his ideas on the following subjects: Please give me your suggestions looking to a series of entertainments that will interest the membership during the winter and early spring months. How do you stand on the question of stated tours during the early summer and fall? Are you in favor of club runs extending to distances that require more than one day to go and return? It is my intention to interest all our members in the ease with which runs for several hundred miles through the valleys of Virginia and Maryland can be attended without risk of failure and with the consequent great pleasure to be derived, as I can attest from an extended experience. The pleasure of automobiling, while it has grown enormously in Washington, is as yet nothing to what it will be in the next few years, and membership in this club will be highly sought with each succeeding year."

President Caverly is to be congratulated on the steps he has taken to awaken interest in the club, and it is evident that during his administration the Automobile Club of Washington is going to take rank with the leading clubs of the country.

A. C. C. of N. J. Wants All Vehicles to Carry Lights.

NEWARK, N. J., Jan. 14.—The Associated Automobile Clubs of New Jersey, at its recent meeting, held at Trenton, appointed a committee to draft a bill to be introduced at the present session of the New Jersey Legislature compelling all vehicles, horse-drawn or motor-driven, to carry lights at night. This committee consists of Frederick R. Pratt, the president of the State body; J. H. Wood, president of the New Jersey Automobile and Motor Club, and George A. Post, president of the North Jersey Automobile Club. It is the intention of the State body to revive an old law upon the statute books defining the rules of the road and the rights of all users of the public highways. The new Legislative Committee of the State association will be announced in the near future.

Quaker City Ladies to Have a Club.

PHILADELPHIA, Jan. 14.—The Ladies' Quaker City Motor Club, composed for the most part of the wives, sisters, cousins and aunts of members of the Quaker City Motor Club, has been organized. At the Hotel Majestic last Tuesday a temporary organization was effected by the election of Mrs. Joseph J. Martin as president, Mrs. Charles J. Swain as vice-president and Mrs. Edward B. Fincke as secretary. Over a score of fair Quakeresses have already signed the membership roll, and the recruiting committee is working with such a will that when the club meets for permanent organization a fortnight hence it is believed that the total will exceed the half hundred mark.

The charter members include Mrs. Joseph D. Bucher, Mrs. Robert A. Pitts, Mrs. Thomas E. Cookman, Jr., Mrs. Harry F. Cook, Mrs. William H. Noblitt, Mrs. Frank M. Chandler, Mrs. William Laycock, Mrs. William Ingram, Mrs. James M. McCartney and Miss Ida Benezet.

The Quaker City Motor Club is arranging for a monster hill climb, to be held on Memorial Day over a course in the neighborhood of Chestnut Hill.

Furnishings for New Chicago A. C. Clubhouse Chosen.

CHICAGO, Jan. 14.—Progress on the new home of the Chicago Automobile Club has not been as rapid as many of the members would like to have it, and in order that, once the building itself is up, no further delay shall be encountered in making the interior ready for the grand housewarming with which the new quarters will be thrown open, President Ira M. Cobe has been planning a surprise for the members. He has been devoting considerable time to hastening the work on the big building that is going up at 13-15 Plymouth court, and has just issued an official prospectus showing how the interior of the clubhouse will look when it is finally ready.

Starting with the basement Mr. Cobe has selected for the grillroom furniture of Mission style finished in green oak. The walls will be cement, marked off in squares to imitate stone, being set off at the top with a wide frieze depicting various colonial scenes, the subjects of most of which, it is expected, will be drawn from the history of the early days of Chicago. The bowling alleys will also be on this floor and will be of the most modern type in everything that concerns their construction and equipment. The color scheme in the latter will harmonize with that of the grillroom. On the second floor there will be a lounging room furnished with large arm chairs finished in old Spanish leather. At each end of the room there will be a large fireplace, the color scheme of the room itself being in green of two shades. On the same floor there will also be the ladies' parlor, furnished with furniture of the style of Louis XV., which will be brought from abroad. This room will be decorated in paneling of the same style, the color scheme being in French gray. The floor above will house the main cafe, which will be finished in paneling, the color scheme also being French gray and Pompeian red, while two entire floors will be devoted to sleeping apartments, which will be furnished with brass beds and mahogany furniture throughout.

Bay State A. A. Elects Officers, and State Organization Meets.

BOSTON, Jan. 4.—Pronounced interest characterized the largely attended annual meeting of the Bay State Automobile Association at the clubhouse on Dartmouth street January 7. Reports presented by officers and committees showed that the association is in excellent shape financially and socially. President Lewis R. Spere in his report reviewed the work of the year. Secretary James Fortescue reported that the association now has 700 members and is in a prosperous condition. With the increase in dues, which goes into effect this year, it is expected that the treasury will be enriched by several thousand dollars annually. In the election of officers very few changes were made. President Spere, Vice-president Harlan W. Whipple and Secretary Fortescue were reelected. Harry Knights was chosen treasurer in place of Herbert L. Bowden. The new board of directors is as follows: Charles E. Fay, of the Ford Company; J. C. Kerrison, Arthur Hinchcliffe, of the Winton branch; A. P. Underhill, of the Reed-Underhill Company, and George W. McNear, of Quinsler & Company.

Before the Bay State meeting there was a meeting of the Massachusetts Automobile Association, attended by President Elliot C. Lee, of the Massachusetts Automobile Club; President L. R. Spere, of the Bay State A. A.; President J. P. Coughlin, of the Worcester Automobile Club; President Haynes, of the Springfield Automobile Club; Charles Leonard, of the Leominster Automobile Club, and Treasurer J. C. Kerrison. The proposed legislation in Massachusetts was discussed and plans were also considered for the conduct of the association under the new rules of the A. A. A.

The Greatest American Automobile Show. Seven years of automobile shows, each one so much better than the last, both in point of the achievements exhibited as well as the manner in which they have been staged, have led New York and the automobile industry as a whole, which sends its representatives by the thousands to attend the metropolitan event, to expect a great deal. Seldom has expectation been more completely fulfilled. The history of the past seven years of automobile show-holding has been so frequently reviewed of late that it would be superfluous to attempt to recount it here, but the paucity of material available as well as the crudeness of its surroundings, as installed in the first event of the kind, may well be recalled at the moment when the magnificent spectacle presented by the Garden during the current week is holding the attention of the automobile world, which is daily embracing a greater and greater proportion of the general public.

Planned almost a year in advance, the matter of providing an appropriate setting that should surpass anything of the kind hitherto attempted—a task involving a vast amount of labor and a large expenditure—has been so carefully carried out that not a detail was lacking to mar the completeness of the picture when the doors were thrown open Saturday night. Never has the automobile appeared to better advantage. The show as it stands is a fitting culmination of seven years of persistent effort, which will be found difficult to surpass on future occasions, regardless of the amount of time or money that may be devoted to the work of converting the bare walls and ceiling of the building that houses it into a scene, every detail of which becomes blended in the complete ensemble.

As for the cars themselves, it would be difficult to add to what has already been said many times over regarding the advanced stage of construction and design that they represent. American builders were slow in grasping the essentials of design as established by their forerunners abroad, and for a long time were unwilling to admit superiority when they saw it; but, once the period of indecision was past, progress came so fast that the original handicap was soon made up and the mark set by it left far to the rear. Nothing exemplifies this better than the present show, in which the flower of automobiledom, as represented by the chief makers on either side of the Atlantic, are ranged side by side. Time was when "imported" stuck out all over the foreign production, and it was akin to crossing a frontier merely to go from the stand of a home builder to that of one of his competitors from across the pond. How completely the distinction has disappeared could hardly be better evidenced than by the frequency with which the exhibitors' signs and the nameplates on the cars themselves are called upon to identify their country of origin. Dollar for dollar, there is nothing superior to the American car in whatever light it may be considered, and, after all, that is the crucial test of worth.

Present Status of the Two-Cycle Principle. Compared to the number of years that were required to develop some of the best known inventions in other lines of industry, the amount of time that has been devoted to a practical study of the problem presented by the evolution of the two-cycle principle of the internal combustion motor is but a mere bagatelle. Yet there are critics who point to the fact that during the seven or eight years in which the two-cycle motor has been a factor in the automobile industry, but one firm has had the courage of its convictions. That but one builder has consistently adhered to this principle in building automobile motors is a matter of common knowledge, but that this is to be considered as being conclusive proof of its unfitness for the purpose in question would be absurd. Had it not been for the dogged persistency of some inventors in adhering steadfastly to their ideals in the face of ridicule, the advent of numerous time and labor-saving inventions might have been postponed indefinitely. Daimler himself was regarded as a harmless lunatic for attempting to combine a gas engine and a carriage, but it is safe to say that had he not persisted the automobile would not have been so far advanced.

Between those extremes of optimism that predict the final arrival of the two-cycle motor at a stage where it will have swept all before it, and that of the reverse, which considers the time and money spent on the further development of the principle as utterly wasted, there is a sane medium which is representative of some of the best talent in the industry. Both the possibilities, which are great, and the difficulties, none of which are insurmountable, are recognized, and that the former will, in time, be realized to a far greater extent than they are at present is a foregone conclusion. That the two-cycle motor in its present stage of development, as represented by the power plant of the cars turned out by the firm specializing on this principle, is an efficient and practical machine will not be denied by anyone who is familiar with its capabilities, not to omit its long record of extremely creditable performances under conditions calculated to test the merits of any piece of machinery beyond the breaking point. That it has been able, not alone to survive these, but to come out of them in a manner not less creditable than was displayed by others of the standard type, is indicative of the promise its further development holds out. Whether, in the end, the principle will be proved to represent the only path to that extreme of simplicity, combined with a high degree of efficiency that is the aim of every designer, is something that cannot be predicted. Suffice it to say, its past shows what can be done, and if more initiative were taken there is little doubt that its position in the automobile world would be more rapidly advanced. It is with this in view that we have encouraged a statement of opinion on the subject.

THE MUNCHAUSENS OF AUTO PUBLICITY.

Little Hungary, a well-known Bohemian resort in East Hous-ton street, Tuesday night held a noted assemblage of disciples of Munchausen, whose tales were the wonder of his time. The publicity experts of automobiling sometimes travel faster than the cars whose deeds they exploit, and for purposes of mutual offense and defense they organized under the somewhat startling title of "To H—l with Booming Anybody Society, Limited." "Confidentially," states Duncan Curry, "they told each other what they thought of the automobile game in general and each other in particular."

These were the notables gathered round the festive board: E. Ralph Estep, Packard; F. L. Faurote, Oldsmobile; R. H. Johnston, White; H. T. Clinton, A. L. A. M.; Charles W. Mears, Winton; Leroy Pelletier, Ford; George Bolles, Royal; H. W. Grant, Maxwell; J. A. Kingman, Locomobile; T. F. Moore, Wyckoff, Church & Partridge; W. L. French, Matheson; Charles Culver, Knox; R. L. Dunn, Pope; George T. Davis, Thomas; J. W. Drown, Corbin; C. H. Rockwell, Autocar; A. B. Tucker, a wholesaler; F. Ed. Spooner, another wholesaler; C. H. Huntington, Columbus; Alex. Schwalbach, Brasier; Jack Hitchcock, of Philadelphia; Joe Ryan, of Chicago. Of course, Press Agent Arthur N. Jervis, of the Garden Show, was a prominent figure, and Alfred Reeves, general manager of the A. M. C. M. A., attended the function, of which "Billy" Young served as bouncer, though his services were not called into play.

A. C. A. PRESIDENTS JOIN THE "FINEST."

Entitled to be equipped with a billy, a regulation six-shooter, and a badge issued by the Municipal Police Department, five members of the Automobile Club of America will henceforth have the weight of law and authority on their side, and will make it their business to arrest for overspeeding and reckless driving wherever they see it. They are President Colgate Hoyt and ex-presidents Winthrop E. Scarritt, George F. Chamberlin, David Hennen Morris, and Alfred R. Shattuck. Messrs. Hoyt and Scarritt have already had their applications acted upon favorably by Commissioner Bingham and have been duly enrolled as special policemen of the city of New York, Nos. 27 and 347 respectively.

When approached on the subject, the Police Commissioner was of the opinion that the newly added members to the special "force" would not be compelled to wear uniforms, but they will have to call at Police Headquarters once a month and sign the roll blotter, and in case of riot or emergency they are apt to be called upon at any time to do police duty. This is interesting in view of the fact that it is not a felony to assault a special policeman, though such is the case where a regular guardian of the peace is concerned. If necessary to aid in the prosecution of offenders and aid the police in general in this matter, the club will furnish the services of a lawyer. The A. C. A. intends to do its part in ridding the metropolis of the scorching drivers.

EUROPEAN INVASION TAKES SHAPE.

Preliminary arrangement for the invasion of Europe next June and July, as planned by George Dupuy, were discussed at a meeting at the New York Motor Club, Tuesday. The "invasion" is to consist of a 4,000-mile tour in France, Italy, and other countries by fifty or sixty American automobiles. An American Gold Cup for the trip will be donated by W. K. Vanderbilt, Jr., E. R. Thomas of Buffalo, Jefferson deMont Thompson, and other automobile sportsmen. Several important manufacturers have expressed their approval of the tour, and E. R. Thomas, of Buffalo, and W. J. P. Moore, of New York, have signified their intention of entering cars. An organizing committee has been appointed, consisting of E. R. Thomas, chairman, George N. Pierce, A. L. Riker, J. D. Thompson, H. A. Lozier, E. S. Partridge and W. J. P. Moore.

BRUSH RUNABOUT CO., OF DETROIT.

DETROIT, MICH., Jan. 14.—Detroit's ever-thriving automobile industry has given birth to another member of the rapidly-increasing family, in the Brush Runabout Company. This firm, which was recently incorporated in New Jersey, with \$200,000 capital, will shortly commence operations in this city. The concern has purchased the control of the Eclipse Manufacturing Company, of Fort street east, which will be converted into a foundry where engines will be manufactured, the other parts and assembling to be done at the Briscoe Manufacturing Company.

As the name of the company implies, attention will be paid to the construction of runabouts only. The new factory, encouraged by the success and popularity the \$500 Ford runabout has attained, will enter a competitive field and plans to put a run-about on the market at as low a price as has the Ford. Distinctive features from the Ford type will be a single cylinder vertical engine and solid tires. A. P. Brush, who is connected with the firm and who will be designer, will be remembered as the man who made the Cadillac single cylinder famous.

A number of well-known local and eastern capitalists are behind the project, which should assure ultimate success. The officers of the company are: President, George B. Yerkes; vice-president, F. A. Harris; secretary, Emil D. Moessner; treasurer, A. C. Miller.

Though the new car has been shown in private to those directly interested, it will not be put on public exhibition until the Detroit automobile show. The general design of the engine, the lightness of reciprocating parts, combined with its relation to the spring suspension, renders the vibration almost unnoticeable, and the noise is reduced to a minimum. By moving the hood all vital organs of the car are uncovered. The cars will be ready for delivery about April 1, and will be shipped at the rate of fifteen a day till the season's run of 2,500 is delivered. Six thousand is the figure for 1908, after which date 10,000 cars will be turned out yearly.

PERCY OWEN TAKES ON A FOREIGN LINE.

Percy Owen, for many years identified with the selling end of the Winton interests, and for the past year or so eastern sales manager of the Aerocar Company, has just severed his connection with the latter concern to undertake the general sales agency in this country of the Bianchi car. The latter is an Italian production, designed on lines made familiar by the Mercedes and Fiat cars, and is built by one of the largest concerns in the Peninsula. Three chassis, of 30, 40 and 70 horsepower respectively, are listed. A New York branch has just been opened at Seventy-first street and Broadway, and Mr. Owen expects to sail for Italy before the end of the month to hasten deliveries. The company is building three high-powered racing machines.

GEORGE H. DAY GOES SOUTH TO REST.

Owing to the long-continued strain he has been laboring under in attending to the executive work in connection with this week's show, George H. Day, general manager of the Association of Licensed Automobile Manufacturers, has been ordered South by his physician to rest. The latter considered that he was in danger of physical breakdown several days before the opening of the show, but Mr. Day insisted upon remaining long enough to get at least a glimpse of the fulfillment of the task that he had been so largely instrumental in carrying out. He left after attending a meeting of the executive committee Monday afternoon.

AUTOMOBILE TIRE COMPANY OF TRENTON, N. J.

A newcomer to the tire field is the Automobile Tire Company, of Trenton, N. J., in which several well-known automobile manufacturers are said to be interested. C. H. Semple has accepted the presidency of the new company, having resigned as general sales manager and secretary of the G & J Tire Company, of Indianapolis, Ind.

QUICK SETTLEMENT ON A. C. A. SHOW.

The seventh annual Automobile Show of the Automobile Club of America, participated in by the members of the American Motor Car Manufacturers' Association and the Motor and Accessory Manufacturers, and also open to other automobile manufacturers, closed its doors but a month ago. A financial statement has just been published showing a net profit of \$52,000. In accordance with the profit-sharing policy of the exhibition committee of the A. C. A., one-half of the net proceeds of the show, amounting to 45 1-2 per cent. on the amount of space rental paid, will be refunded to exhibitors. Members of the A. M. C. M. A. also benefit by the preliminary association rate of 20 per cent. below the regular figure, making a return of 65 per cent. on price paid for space. This is said to be a larger refund than has ever been made to exhibitors in any automobile show held in America.

MINNEAPOLIS SHOW, MARCH 2 TO 9.

MINNEAPOLIS, MINN., Jan. 14.—The Minneapolis Automobile Dealers' Association has secured the new First Regiment Armory for the first automobile show ever held in the Northwest. The show will take place during the week of March 2-9, under the managership of an expert from the East, and will be the most pretentious ever held west of Chicago. The Western Passenger Association has granted a railroad rate of a fare and one-fifth, for the entire Northwest country. The sum of \$3,000 has been pledged by the Minneapolis dealers who are behind the show, and \$5,000 will be subscribed if necessary for the work of organizing the big exhibition. Negotiations are on with an Eastern show manager, to take entire charge, and no effort will be spared to make it an unqualified success. The Armory has but recently been completed, and the exhibition will be one of the first public functions to be held in it.

BUFFALO'S SHOW IN CONVENTION HALL.

BUFFALO, N. Y., Jan. 14.—Arrangements have been completed for the automobile show to be given this year under the auspices of the Automobile Club of Buffalo and the Buffalo Automobile Trade Association. Space allotments were made last Thursday. Secretary D. H. Lewis had much difficulty in obtaining Convention Hall, but finally secured the place for the week of February 18-23. The electrical display will be one of the features of the show. One piece alone will contain 1,000 lights.

At the recent annual meeting and banquet of the Buffalo Automobile Trade Association the following officers were elected: President, J. A. Cramer; vice-president, W. C. Jaynes; secretary, D. H. Lewis; treasurer, J. J. Gibson; executive committee, E. C. Bull, J. B. Eccleston, and G. H. Popenberg.

COAST AUTO SHOW IS PLANNED.

San Francisco will hold its first automobile show the latter part of February in the new skating rink near the Golden Gate Park, a building having more than seventy thousand square feet of show space. The proposition to hold a show met with instant favor among local dealers, more than thirty being present at the first meeting. Arrangements are being perfected rapidly by the dealers, assisted by the Automobile Club of California. The following officers have been elected: President, J. W. Leavitt; secretary, Herbert Choynski; manager, Max Rosenfeld.

IMPORTERS HOLD A RIVAL SHOW.

In a cleaned-out Fifth avenue picture gallery several importers are holding their "show" concurrently with the one in Madison Square Garden. The exhibit consists of a Renault runabout and a Renault touring machine, both last year's models; a Westinghouse, with double phaeton body and a 30-horsepower chassis; a Delahaye chassis, a pullman and a landaulet; a Cottin-Desgouttes, and a Pilain chassis.

GLIDDEN MILEAGE NEARLY FORTY THOUSAND.

BOSTON, Jan. 14.—Mr. and Mrs. Charles J. Glidden, the world girdling automobilists, accompanied by Miss Martha Waldron Barron, of Boston, have returned after their disastrous experience in touring on the railroad tracks in Mexico. They left here in Mr. Glidden's Napier two months ago, and since then have traveled 6,168 miles, of which 5,022 miles were on railroad tracks. Mr. Glidden's car was derailed near Mexico City and wrecked. He has had it shipped to England for repairs, and next season will tour in the British Isles. Speaking of the wrecking of his car, Mr. Glidden says that nobody was to blame.

"We were running twenty-eight miles an hour," he says, "on a straight track when a rock wedged in between the main track and a guard rail was struck by the flanges of the left wheels, and we jumped the rails and ran about ninety feet. The forward wheels collapsed, and we were all spilled out, but no one was injured. Had not the wheels collapsed the car would have run up on a bank, overturned, and undoubtedly buried us all underneath with serious results. I tapped the telegraph wire, put on a set of instruments that I was carrying, and immediately opened up communication with the train despatcher at Mexico City, securing assistance in a short time in the shape of a special train. We arrived in the city of Mexico on the time planned before leaving Boston, December 31."

CINCINNATI'S SHOW AND ENTHUSIASM.

CINCINNATI, Jan. 14.—Cincinnati's first automobile show will take place January 21-26, and will be held in the Fireproof Storage Company's building, at the intersection of Walnut Hills and Avondale, two of the Queen City's wealthiest suburbs. All the space has been taken by exhibitors. There will be forty-seven different makes of cars shown by the twenty or more dealers of the city, who organized under the name of the Cincinnati Motor Car Dealers' Company for the purpose of bringing Cincinnati to the front as an automobile town. Besides the cars shown, moving pictures of the Vanderbilt Cup race, and two of the cars that took part in that event, will be seen.

It will be remembered that a few years ago pessimistic people asserted that automobiles would never find favor in a town that was "built upon seven hills." The sale of automobiles for the year 1906 was 100 per cent. more than the previous year.

THE PROFESSIONAL CHAUFFEURS' CLUB.

At the annual meeting of the Professional Chauffeurs' Club of America, held at the clubrooms, 1775 Broadway, New York City, the officials for the year 1907 were elected as follows: President, W. H. Walter; first vice-president, Fred Brevogel; second vice-president, Curt Schmidt; treasurer, W. H. Chase; recording secretary, George Loveday; corresponding secretary, P. A. Larter; governors, O. J. Byers, F. Engelsberg, F. Walsh, L. Regan.

The club has a membership of 250, is strong financially, and is looking forward to a successful year and a new clubhouse in the fall, the present quarters proving entirely inadequate.

BALTIMORE'S CLUB AND BALTIMORE'S SHOW.

BALTIMORE, Jan. 15.—With the indorsement of the Automobile Club of Maryland, which has taken over the second annual show, which will be held at the Lyric, January 21 to 26, there now seems to be no doubt that the event will be one of the largest of its kind ever held in the South. Many new features have been arranged for the show this year, and more will follow visits to the New York show by the committee appointed to attend the mammoth show in New York this week in the interest of the local show. Notwithstanding the fact that B. R. Johnson, manager of the show, succeeded in obtaining one of the largest halls in Baltimore, they will be cramped for room according to the number of exhibitors, which now nears the fifty mark. The pictures of the Vanderbilt Cup race and several other events will be shown.

THE
CONTINUATION
OF THE
GARDEN SHOW
STORY

EXHIBITS OF VARIOUS KINDS.

Auto Improvement Company.—At this exhibit is shown an extensive line of auto sundries both for use on the car and in the garage. The line includes the "Ever Ready" tire tool, for putting on and removing clincher tires; vulcanizers for use both on the car and in the garage, and the "Ever Ready" carbureter, the special feature of which is that it is especially adapted for the heavier liquid fuels. It is provided with two jets and float chambers, one of which can be used for a light grade of gasoline and the other for the heavier fuel after the engine is started.

H. A. Allers & Co.—This firm exhibits "Solarine" metal polish in both the powder and liquid form. Faith in the merit of the article is shown by giving away samples.

Avery Portable Light Company.—The ability to merely turn on the gas whenever wanted and turn it off ditto, without having to fuss with carbide or the necessity for cleaning out a generator, has appealed so strongly to the average autoist that the lighting tank long since came to be considered an indispensable part of the equipment of the up-to-date car. On this account the exhibit made by this company is a reminder to the visitor of what he has been saved by science.

Brennan Motor Manufacturing Company.—This concern shows a line of motors and transmissions ranging from a two-cylinder horizontal opposed to a four-cylinder water-cooled with mechanically operated inlet valves. The concern makes various sizes, both air and water cooled. The transmissions include both the two-speed planetary and the selective type for either side chain or shaft drive. Both transmissions and motors are furnished with annular ball bearings if desired.

Energine Refining Company.—This company exhibits samples of its Energine fuel for automobile and motor boat use of which it is the sole refiner. This fuel is claimed to possess the advantages of greater power than is obtainable with gasoline without the drawbacks of the latter, not the least of which is its objectionable odor.

General Electric Company.—The exhibit of this company is a magnet that attracts every visitor that comes its way to note the operation of the Mercury Arc rectifier, which is shown in operation. In the three years that this device has been on the market, both for public and private garages, where nothing but an alternating current service is obtainable, it has become too well-known to require description. It has met with wide-spread acceptance which is becoming greater as its advantages are better understood.

Globe Machine and Stamping Company.—Every variety of automobile part has been produced by this firm since the automobile industry came into existence. At their stand, which was in charge of Albert F. Schroeder, general manager, and O. A. Loew, chief mechanical engineer, are to be seen ball races, retainers, brakes, brake drums and bands, hub cups and flanges, gaskets, fan blades, sector tank heads and heavy metal, shallow shell and thin metal deep shell stampings in general. Not the least item

of interest in the Globe exhibit is a few sample sheet shells or caps with internal threads. The unique feature is the fact that the threads had been generated on a punch press.

E. F. Hodgson.—The autoist who has been confronted with the problem of where to stow his car without going to the expense of putting up a building and disfiguring his grounds in the process finds that his difficulty disappears at this stand. The problem is solved by the Wigwam portable garages and houses shown by this manufacturer.

Pantasote Leather Company.—This is an exhibit that interests the manufacturer of cars and will as long as leather upholstery continues to be the standard finish for the interior of the up-to-date car. Leathers of this make of every imaginable shade and texture are shown, all of them being finished with a surface especially adapted to withstand the severe usage given the upholstery of an auto.

Thos. Prosser & Son.—This firm is the agent for Krupp Special Chrome Nickel Steel, which they supply in either finished parts or in the rough. The exhibit includes a line of finished and partially finished parts as well as chips and parts which have been bent and broken to show the qualities of the metal.

Springfield Metal Body Company.—This firm shows a number of up-to-date styles in aluminum bodies, in addition to a line of special tops, the construction of which is patented.

Spicer Universal Joint Manufacturing Company.—The rapid increase in the employment of the shaft type of drive has brought with it an unusual demand for universal joints, of which those shown by this firm are representative examples. They are distinguished by extreme simplicity and generous proportion of working parts that makes for durability and satisfactory service, no nuts, bolts, screws or other fastenings being employed in their design. A number of styles are shown, such as the combined joint and brake drum, a universal slip joint with flange coupling, also double universal joints and complete sets.

C. A. Shaler Company.—This firm shows the Shaler electric vulcanizer, which is adapted for repairing cuts in shoes and also punctures in tubes. The device can readily be connected to any alternating or direct current incandescent circuit, is economical of current, and can be carried even in a light runabout without inconvenience.

Valentine & Co.—This firm exhibits a line of colors and varnishes suitable for automobile work. The company's long experience in supplying goods of this description to the carriage trade is a guarantee of the quality.

DEALERS IN GENERAL ACCESSORIES.

Auto Supply Company.—This concern displays a representative exhibit of the best known makes of accessories and they are also importers of a complete line of French ammeters and volt meters as well as goggles. In addition to the array of

smaller accessories, they also carry a complete assortment of engines, transmissions, differentials, wheels, forgings, and parts of well-known makes for builders, assemblers, and repairmen.

Charles E. Miller.—The very name Miller stands for everything that pertains to the automobile. For lack of space his exhibit is confined to the smaller and more portable types of goods, but there are more where they came from. In fact it would be easy in an hour or two with Miller's vast stock at one's disposal to pick out the components of an entire car from the ground up, including every possible accessory that could be put on it. Motors, transmissions, drives, wheels—everything in short that goes to make up an automobile, is handled by Miller.

Motor Car Equipment Company.—It is difficult to know where to begin in attempting to describe the multi-varied stock displayed by such a firm as this, covering as it does a range of supplies running from cotter pins up to tires, lamps, clothing, batteries, and what not, all of which are shown in what appears to be a practically endless array, a great many makes of the same thing such as speedometers, accumulators, and the like, representing the product of the best known makers being carried.

New York Sporting Goods Company.—As its name indicates, this concern specializes more on the accessory end, handling more particularly such lines as lamps, accumulators, dry cells, ammeters and voltmeters, tires, clothing, and the like of representative makes, of which it shows a comprehensive assortment at its stand.

Post & Lester.—This concern has the distinction of handling one of the most representative lines of imported automobile accessories to be found in this market, in addition to as complete an assortment of domestic supplies as it is possible to imagine. Some of the specialties from the other side are the well-known Volier horns and the E.I.C. racing spark plugs.

AUTO HORNS AND CHIMES.

Gabriel Horn Manufacturing Co.—The chief feature of this firm's display is the 1907 model of the Gabriel horn, which consists of but a single tube instead of the multi-tube types formerly popular. It gives three distinct tones blended harmoniously, the regulation of the tone being readily controlled by the operator at will. As the demand for the three-tube horns with two-inch tubing and the four-tube with 1 1/2-inch tubing is large, these types are continued, and various models are shown.

Gray-Hawley Manufacturing Company.—This concern displays the patented Autochime device to be used in connection with the auto muffler. It is a practical three-tone chime of extreme simplicity, involving no delicate or complicated parts in its construction. It is shown separately and in connection with the Gray muffler, making a complete combination outfit. Motorchimes and chime whistles are shown.

CLOTHING AND GLOVES.

Morrison, McIntosh & Company.—The Grinnel ventilated and air-cooled "rist-fit" gloves and gauntlets comprise the specialty displayed by this concern in a number of styles designed with a view to meeting the needs of auto and other drivers. The material employed in their construction is "reindeere" leather, and the special design keeps the hand cool in warm weather and still excludes oil and dirt.

Syracuse & Elbridge Glove & Mitten Co.—As their name indicates, the display of this concern consists of a full line of specially designed hand coverings for the auto driver.

Syracuse and Elbridge Glove Company.—This concern makes a specialty of automobile gauntlets. These are made with reinforced palms and fingers and also are arranged so that the seams are protected from wear; in short, it is claimed that the glove is especially suited to the hard use which it must necessarily stand when worn around an auto.

CASTINGS.

Light Manufacturing & Foundry Company.—Probably no other firm, in this country or abroad, has specialized to the same extent on aluminum castings as has this concern—a fact that is recognizable in the showing of its products. It is not going too far to say that their success in turning out crankcase and gearbox castings, entirely free from flaws and defects, and at the same time with a use of the minimum amount of metal, has contributed very largely to making the high-powered motor for automobile use a possibility.

Manufacturers' Foundry Company.—At first sight it appears almost inconceivable to the layman that the intricate shapes given the cylinder of the up-to-date motor with its water-jackets surrounding the valve pockets, could be reproduced in such a material as cast iron with the clean and accurate lines that distinguish the work shown by this company, of which a number of examples are on display, several of them being cut sectionally, so as to reveal the uniformity of the metal throughout as well as its entire freedom from blowholes or other defects that would be apt to render it worthless.

WHEELS AND RIMS.

Midgley Manufacturing Company.—Tubular steel wheels constitute the manufacturing line of this company. Starting from the point that a wire wheel did not look right and a wooden wheel did not work right, the Midgley company set to work to produce something which would look like a wood wheel and work like a steel one. The Midgley is made wholly of steel. Its process of manufacture is to first cut the sheet metal into proper sizes and form it into required shape under heavy presses. The rims or channels are formed under a specially built press; the under body or felloe is formed in the same way, and after the spoke holes have been punched the two are clinched together. The several parts are brazed together, the entire wheel being immersed in a molten bath of brass which flows into every corner and covers every surface with a layer of the metal. This makes the wheel one single piece; there is not a separate bolt pin or rivet in it.

Schwarz Wheel Company.—Patent wooden artillery wheels occupy the attention of the Schwarz company. A difficulty in wood automobile wheels has been the tendency to loosening of spokes under strain, the wheel becoming shaky, ceasing to run true and finally becoming useless. In the Schwarz this is overcome by the construction of the spoke, the tenons of which interlock in a fashion to render them utterly immovable. The spokes are put together at one time under pressure, each interlocking with its neighbors. Distances between the spokes are mathematically the same throughout. No hub flanges are required in making the wheel; they can be put on at any time, but are practically unnecessary until the wheel is to be put on the axle. The fact that the wood wheel may be made complete, the metal rim or channel for the tire put on, and the entire product shipped without a hub must commend itself to the practical observer.

Phineas Jones & Co.—Half a century of experience in wheel building is a record to be proud of, and that it is one that has brought with it the "know how" of the business of making wheels of the right kind, no matter how hard the service to which they are to be subjected, is plain from the attractive exhibit made by this firm of a part of the car of which the average autoist rarely thinks, except when it happens to cause him trouble.

Turner & Fish Company.—Indestructible steel wheels manufactured by the Turner & Fish Company have the advantages of durability, being absolutely true, easily cleaned, collecting less mud and dust than spoked wheels. The wheel is made of two sheets of high-carbon, two-pass cold rolled steel, each sheet being drawn and formed in a skilled way. When the disks have been formed the rivet holes are punched and the halves are then riveted together, practically making a solid background for the spokes. The wheel is now ready for the hub and rim. Three

gauges of metal, weighing from 11 1-2 to 19 pounds to the wheel, are used in manufacture, making it applicable to all sizes and weights of automobiles, and having a carrying capacity of 15,000 to 50,000 pounds.

Standard Welding Company.—Seamless steel rims for all types of wheels and rims are manufactured by the Standard Welding Company, Cleveland. Regular lines comprise standard clincher rims for wood or wire wheels to standard patterns used by all tire manufacturers; standard steel rims for single tube tires having crescent, drop center or flat base. In addition, any special rim can be made to blue prints and specifications. All rims are made true to circle, with properly flared edges, and are guaranteed against inherent defects. By the Standard Welding Company's methods absolute uniformity in circumferential measurement and perfection of tire set are assured.

CARBURETERS.

F. E. Bowers Company.—The Bowers carbureter, about to be put on the market by the F. E. Bowers Co., New Haven, is a new instrument of the float feed type, having one main and two supplementary air inlets. A constant level of gasoline is maintained by an annular metal float acting upon a needle valve by means of a trip. The distinguishing feature of the carbureter lies in the air supply. All air passing through the main inlet is thrown directly upon the spray nozzle, causing a uniform mixture. The base of the mixing chamber is a cone through the summit of which passes the spray nozzle. Over this cone is placed a copper funnel-shaped vessel, the base of which forms a cone fitting round the cone base of chamber, but leaving a space between the two. Air from the supplementary inlets is drawn up between the two cones and thrown directly through the gasoline

line spray; consequently the gas is completely formed before leaving the carbureter. The instrument is only made in one size, but to obtain a larger or smaller volume it is only necessary to change the copper double cone within the mixing chamber, an easy matter owing to it merely being carried by a flange, and make necessary nozzle and air adjustments. The throttle is of the revolving shuttle type giving a central draught at all openings.

Wheeler & Schebler.—In addition to their showing of the Schebler standard, Model "D" carbureter, which is made in seven sizes ranging from half inch to three inches, and which is adapted to fit any make of automobile or marine motor on the market, this concern has just uncovered a new type which is termed Model "E." This is a Schebler special type made with bottom air draft, the latter constituting the fixed air opening while the auxiliary opening is entirely closed when at rest, in distinction to the standard model in which the same inlet provides both the main and auxiliary air supply. The new model also differs in being equipped with an arrangement for taking hot air from the exhaust of the motor. The price of this carbureter is slightly higher than that of the standard. In addition this firm shows a balance throttle adapted to be fitted to any size of their carbureters, when using a governor, as well as a line of check valves for use in connection with two-cycle engines, these being also universally adaptable.

Byrne, Kingston & Co.—This concern exhibits a very com-

plete line of carbureters adapted for all classes of work, automobile, stationary, and marine. The company has a large line of mufflers, either plain or fitted with cut-outs, adapted for all purposes.

Holley Bros. Company.—This company has a variety of carbureters, mostly of the central draft type. One of the specialties is a carbureter having the air intake at the top. This type is especially suited for marine work, where the carbureter must necessarily be placed low down.

The National Sales Corporation.—This concern is agent for the New Gaither Owen carbureter. The peculiarity of this device is that the intake pipe and mixing chamber is formed of a closed spiral spring which it is claimed tends to more thoroughly mix the gasoline vapor and air as well as form an automatic air valve.

The Heath Dry Gas Company.—This concern has perhaps the most striking novelty in the show, as its carbureter is without a float chamber, and depends solely on a suction valve to regulate the supply of gasoline between impulses. The strongest feature is a small fanwheel in conjunction with a coarse wire mesh, which it is claimed mixes and vaporizes the gasoline vapor much more thoroughly than is done in the ordinary form of carbureter.

GASOLINE AND OIL TANKS, PUMPS, ETC.

S. F. Bowser & Company.—With their gleaming metal trimmings and highly polished hardwood, the Bowser gasoline cabinets prove a potent attraction and seem better fitted to adorn a drawing room than a garage. The principal features of the exhibit are the Bowser combination cabinet, the Bowser long-distance outfit and the Bowser wheel tank. A booklet entitled "Just a Moment" has been prepared especially for distribution in connection with the exhibit and calls attention to the specialties shown.

National Oil Pump & Tank Company.—This firm displays a number of gasoline storing and pumping outfits for garages of all sizes, from its Little Hercules size up. Included in these is a long-distance outfit, a runabout tank and measuring pump outfit for garage service, to permit of the tank being taken to the car instead of the reverse, and the National automatic measuring power pump.

The Detroit Lubricator Company.—This concern shows the Hodges force feed oiler. This consists of a multiple feed individual pump type of oiler. They are supplied either self-contained or arranged with the sight feeds to be placed on the dash. The peculiarity of this device consists in having the delivery and suction valves positively operated by the operating shaft. It is an efficient oiler of the mechanical type now so generally favored by the majority of American builders of cars.

CHAINS.

National Sales Corporation.—This firm is the exclusive American representative for the Peugeot chains and rims which form the standard equipment of a number of the leading French machines. A full line of the various sizes and types in which these chains are manufactured is on display, in addition to the many other specialties controlled by this concern, such as coils, timers and other ignition accessories.

Diamond Chain & Manufacturing Co.—The products of this house are too well known to call for much description. The name diamond has been associated with the manufacture of chains so long that in this connection they are almost synonymous. Included among the extensive line of chains shown is a new series made of chrome nickel steel, rendering them extremely strong and light. In addition the Diamond I-beam front axle and hubs are displayed in a manner best adapted to show their numerous good points.

Baldwin Chain & Manufacturing Co.—In addition to the line of Baldwin block auto and machinery chains, as well as chains for motorcycle and bicycle use, this firm displays the Baldwin improved spring recoil check and the McKinney removable tire holder, a fixture for carrying spare tires. A full line of Baldwin roller chains, in both detachable and riveted types, is also shown.

Whitney Manufacturing Company.—Chains of every imaginable type form the bulk of this firm's display, including a number of forms specialized by them and with which their name is linked. Beside this array of power transmitters for every conceivable use, there is a complete showing of the Woodruff patent system of keying which has been adopted by a number of prominent automobile builders.

Charles E. Miller.—Brampton block and roller chains, considering the number of special sizes and types in which they are made, are a line of no mean proportions in themselves. They constitute one of the few, if not the only line of this kind brought from abroad and are shown in a variety of styles adapted to practically every car either made in this country or imported from abroad that uses the chain type of drive.

TOPS AND HOODS, ETC.

Sprague Umbrella Company.—No less than five different styles of auto fronts are displayed by this firm, whose name is inseparably connected with the making of tops. In addition a full sized top, covered with leather and lined with red English cravenette, is shown. Four of the fronts are steel and one solid pressed brass, all being enameled in different designs. Beside the above the new Sprague steel bows, adjustable hood and rubber bumpers are in evidence. The demand for the fronts is already large and preparations are being made to manufacture a large number of them.

Vehicle Apron & Hood Company.—Using the well-known "Blizzard" rubber cloth, this firm manufactures a complete line of tire and inner tube cases, tool rolls, top and lamp covers, auto buckets, caps with rain capes, auto shirts, sleeve protectors, dust hoods, auto robes and storm fronts, types of all of which are on view. They also show a non-skid tire band of rawhide and heavy steel rivets adapted to be laced to the tire.

PUMPS, JACKS, TOOLS, ETC.

Wray Pump & Register Company.—On the stand of this concern is to be found that greatest of essentials that should never be left behind but which is sometimes missing when most needed—the pump for inflating the tires. And as the correct pressure is more than half the battle in tire maintenance, the Wray line of pumps are also shown equipped with that very necessary addition, a compact air pressure gauge showing the result of laboring at the handle. As the work of pumping a large tire becomes very strenuous with the increase in pressure, it is usual to conclude that the tire is hard enough when a pressure gauge would show otherwise.

Duff Manufacturing Company.—Barrett jacks constitute the specialty displayed by this concern, and few autoists realize how much depends upon a good jack. One that makes raising the car difficult in order to remove a tire is a poor investment, and one that is apt to let down without any warning when an investigation is going on underneath the car is a menace. These jacks operate equally well at any angle and are guaranteed to be powerful enough to raise the heaviest car with but the exertion of one hand.

Cooks Railway Appliance Company.—This concern is the successor to the Merrill-Stevens Company, of Kalamazoo, Mich., for many years builders of standard jacks, and exhibits a line specially designed for automobile work, the essentials of light weight, great strength and general convenience and handiness,

both in use and for stowing in the tool locker of the car having received attention.

Oliver Manufacturing Company.—Peerless jacks for touring cars, New Samson jacks for garages and Oliver's E-Z jacks for auto trucks, constitute the line specialized by this concern, a full assortment of each type being shown in an attractive manner at their stand.

Stevens & Co.—This concern show a general line of automobile and repair sundries, the specialty consisting of the Noonan line of tools. Somewhat of a novelty is the Noonan Valve remover and also a valve truer by the same maker.

The Utility Co.—Shows a miscellaneous line of sundries which includes the Utility spark plug, the Crackerjack jack, the Bullard wrench, and the famous hand cleaner, "Gre Solvent."

NON-SKIDS, TIRE COVERS, ETC.

Gilbert Manufacturing Co.—Gilbert automobile fabric supplies and the patented Gilbert spare tire case and adjustable tire holders of highly polished brass that have come into such general use of late form the exhibit of this concern, which, owing to the fact that it was a pioneer in the introduction of accessories of this nature, attract much favorable attention.

Hopewell Brothers.—This firm exhibits a line of goods comprising tire cases, tool bags, tube cases, sleeve protectors and vests, all of which are made from special automobile fabrics. Their tire case is a distinctive type similar to that placed on the market by them last year. The chief feature of the display is a white tire case encircling a bright mirror with the inscription "Admire yourself and the Hopewell" tire case.

Weed Chain Tire Grip Co.—This exhibit is unique in that it represents a showing that is not duplicated by any other in the building. "As necessary as gasoline" is the motto of the makers of this anti-skidding traction device, and when the autoist finds himself in a mud hole with the wheels slipping round helplessly he will agree with it. The same concern expected to be in a position to show a new traction device for commercial vehicles, which, however, was not ready.

Allen Auto Specialty Company.—Allen's tire covers and Allen's polished bronze detachable tire holders are the features of this firm's exhibit. The tire covers are of special material—that is, water, oil and dirt-proof—and are equipped with glove fasteners which permit of putting them on or taking them off in a few moments.

MUFFLERS, CUT-OUTS, ETC.

Byrne, Kingston & Company.—In addition to its numerous other specialties, this firm displays a complete line of Kingston mufflers for both automobile and marine use in a number of varying types, plain or combined with cut-outs, and in sizes adapted to engines of all powers.

Gray-Hawley Manufacturing Co.—Automobile and marine mufflers built on the special lines evolved by this concern form the bulk of its display, which also includes a number of other specialties designed for automobile use, such as air, steam and hand pumps, valves, cut-outs and the like.

DEATH OF A PIONEER QUAKER AUTOIST.

PHILADELPHIA, Jan. 13.—Something of a shock was given local automobile trade circles on Saturday morning, when the sudden death of William Morgan, a pioneer in the industry, was announced. In 1899, in company with Louis, John, Thomas and James Clark, he organized the Autocar Company, and established a factory at Ardmore, serving as secretary and general manager until 1904, when he sold his interests to the Clarks. Later he accepted the management of the Philadelphia Locomobile branch.

NEWS AND TRADE MISCELLANY.

Two thousand skilled workmen are now employed by the Cadillac Motor Car Company, of Detroit. Within a short time the daily product of the company will reach more than fifty cars.

The Tincher Motor Car Company, of Chicago, which has contemplated the establishment of a factory at South Bend, Ind., has been absorbed by the Studebaker Automobile Company, South Bend.

In "The Vanderbilt Cup," which is being produced at the New York Theater with Elsie Janis as the star, are seen four S. & M. Simplex cars. Two of the cars are of the racing type and two are touring cars, 1907 models. One of the Simplex racing cars wins the race nightly, carrying the hero as driver.

Raleigh, N. C., is to have an automobile factory. The Dixie Motor Company, of High Point, one of the suburbs, has been incorporated with a capital stock of \$125,000 to manufacture and sell automobiles, bicycles and all parts and accessories thereof. The incorporators are E. W. Van Brunt, C. L. Dutton and H. A. Megraw, all of High Point, N. C.

The success of the tire and tire repair exhibition of the Minneapolis Automobile Club has induced that body to prepare a series of similar exhibits and demonstrations during the winter months. W. C. Crafts, of the National Tire Repairing Company, of St. Paul, recently demonstrated some new methods in tire repair and gave a short lecture on tire rebuilding.

W. B. Hurlbut, New York, manager of the Packard Motor Car Company, who lately returned from Europe, states that New York is far ahead of Paris in many ways as an automobile center. He says that of the garages in Paris will hardly show the same floor space as any one of a half dozen New York garages. The streets of Paris are not so crowded as New York with automobiles and commercial vehicles are not nearly as numerous as in New York.

On December 26, 1906, the corporate name of Cook Railway Appliance Company, of Kalamazoo, Mich., was changed to Cook's Standard Tool Company. The ownership and management remain the same. The principal reason for the change of name was that the name "Standard," by which the company's tools and appliances had long been known to the trade, had become such an important asset to the business that it was deemed advisable to protect it by its incorporation into the company's title.

The entire business of the Lozier Engine Mfg. Co., Buffalo, N. Y., has been taken over by the Du Bois Iron Works, Du Bois, Pa., a \$1,000,000 corporation. While retaining the same general appearance, numerous improvements will be made on Du Bois engines; the manufacture of the Simplex steam pump will be continued. Officers of the company are John E. Du Bois, president; W. C. Pentz, vice-president; E. A. Badger, secretary and treasurer; I. N. Hamilton, general manager; C. E. Stuart, sales and advertising manager.

W. A. Rutz will represent the Continental Caoutchouc Company at the Ormond-Daytona races next week. He will have with him a large stock of tires for

emergency equipment of racing cars, and in addition will also have tires suitable for touring cars that will be immediately available for automobilists desiring them. The Continental company announces that for the convenience of any owner tires will be provided at Ormond of the size and style required by the car. provided advance information is filed with the New York headquarters of the company at 43 Warren street.

In the matter of the interference that has been pending before the Patent Examiner in the case of the Premier Motor Mfg. Co. vs. B. A. Gramm, vice-president and general manager of the Logan Construction Company, regarding the proprietary right to a trademark for motor vehicles, involving the use of the words "car" and "quality" in various combinations, a decision has just been handed down in favor of the defendant. The priority of claim is based more particularly on such phrases as "the quality car," "the car of quality," and "that car of quality."

RECENT TRADE REMOVALS.

The Cartercar Company, of Philadelphia, has removed from the Aldine garage to 1519 Belmont avenue.

J. L. Keir, agent for the Renault car and Michelin tires in Philadelphia, will remove to 310 North Broad street in the immediate future.

R. W. Cook & Company, Chicago representative of the Royal Tourist, have taken possession of their new salesroom at 1251 Michigan avenue.

The Detroit Motor Car & Supply Company has leased the store and basement at 230 Broadway, New York City, for a term of years for a salesroom and garage.

The Auto Supply Company, formerly located in the Park Square Automobile Station, Boston, has removed to 14 Columbus avenue, in the motor mart. Manager Samuel Ascher states that the company's rapidly increasing business demanded increased facilities. The new store is one of the best located in the mart.

The George N. Pierce Company, of Buffalo, makes the announcement that the factory and offices of the company have been removed from No. 18 Hanover street to the new factory, No. 1695 Elmwood avenue. All mail for the purchasing and manufacturing department should be addressed to the new location. The new Pierce factory stands on the site of the old Pan-American midway.

NEW AGENCIES ESTABLISHED.

The Autocar Company, of Ardmore, Pa., has placed the agency for the Autocar for Camden, N. J., with C. C. Albertson, of that city.

Fraser & Reynolds, proprietors of the Rittenhouse garage, South Twenty-third street, Philadelphia, will handle the Wayne line in that city during the coming season.

The Northwestern Motor Car Company, of Philadelphia, which is temporarily located at 1943 North Woodcock street, has taken the agency for the Moline car for that city.

Thomas M. Twining, 210 North Broad street, Philadelphia, has closed a contract with the Crawford Automobile Company, of Hagerstown, Md., to handle the Crawford line.

Charles F. Hellom & Company, makers of Invader oils, have opened two branch houses, one in New York City, at 715 Seventh avenue, and the other in Philadelphia, at 648 North Broad street.

R. M. Jones and F. O. Holden are about to take over the Reo agency at the old Jefferson avenue stand, Detroit. The stand has been thoroughly overhauled and is now one of the brightest on the row.

An agency has been established by the Columbus Buggy Company, of Columbus, Ohio, for the handling of their line of electric vehicles, with Maxwell-Briscoe Chase Company, 1407 Michigan avenue, Chicago.

The Cleveland Motor Company has established a branch in Chicago at 1470 Michigan avenue, where they will share a fine salesroom and garage with the Bird Sykes Company. Richard Bacon, Jr., will manage the branch.

The announcement that the Auto Selling and Repair Company had taken up the agency for the Dragon for Minnesota was premature. The Dragon is considering several parties, and decision will be announced shortly.

From Minneapolis comes the news that the St. Louis car agency has been placed with the Auto Selling and Repair Company. The Oldsmobile agency has changed from the Barclay Auto Company to F. G. Winston, Jr., who handled the Olds line in 1905.

Detroit will soon have another automobile selling agency under the title of the Motor Sales Company. The old Northern stand, at 251 Jefferson avenue, has been secured as a garage. The firm will handle De Luxe and Queen cars and is also looking for a light runabout or electric.

Walter C. Martin, proprietor of the Cadillac Company, of New York, Broadway and Sixty-second street, has taken up the agency for the Rolls-Royce automobile, one of the best-known English machines. The Rolls-Royce Import Company will import the chassis only, the bodies being fitted in this country.

Another high-class garage has been added to the long list on Jefferson avenue, Detroit. The company, which is known as the Fee Vincent, is located between Antoine and Hastings, in the heart of the automobile center. Electric vehicles only are handled, the agency having been secured for Woods electric automobiles.

The Dragon Automobile Company, of Philadelphia, announces representation for the Dominion of Canada with the International Automobile Company, Ltd., of Montreal, being done entirely through correspondence and photographs. In the same manner three sample orders were received from different firms in Mexico.

The Western Rubber and Supply Company will handle G & J tires in Southern California, with headquarters at 1010 South Main street, Los Angeles. The company has been incorporated with the following stockholders: R. T. Brian, Guy M. West, H. H. West, C. A. Davis, R. G. Tryon, Thomas McCafferty and W. C. Brian. Guy M. West will act as manager.

The Franco-American Auto and Supply Company, of Chicago, has been appointed sole agent and distributor in all territory west of Buffalo, N. Y., and Pittsburg, Pa., for E. Lamberjack & Co., for Michelin tires, and Leon Rubay, of New York. The company will carry exclusively the Bell pressure pump, Look storage battery, L. & M. tire irons, Alden Speares Sons' cylinder oil, besides all the supplies handled by Leon Rubay, of New York, and E. Lamberjack & Co.'s full line of Michelin tires, round, flat, anti-skid or Samsonized Michelins.

PERSONAL TRADE MENTION.

L. E. Horton has been appointed manager of the Northwestern Cadillac Automobile Company, with headquarters at Minneapolis, Minn.

Joseph Tracy, the well-known automobile driver, has been retained by the Craig-Toledo Motor Company as consulting engineer. Mr. Tracy will shortly be seen driving the new Craig-Toledo roadster, which he will no doubt enter in some of the most important spring and summer events in the East.

Louis Chevrolet, at one time the champion among automobile drivers in America, has entered the employ of the Autocar Company and is at present undergoing a thorough course of instruction in Autocar work at the Ardmore factory. Later Mr. Chevrolet will be connected with the New York Autocar agency at Broadway and Eightieth street.

John L. Poole, who for some weeks has been visiting the several factories of the Buick Company, at Flint and Jackson, will shortly leave New York to take up the management of the company's foreign sales department. Agencies will be established in all European countries. Mr. Poole's headquarters will be in Paris, France, care of the American Express Company.

T. F. Byrne has been appointed manager of the Chicago branch of the H. H. Franklin Manufacturing Company. Mr. Byrne is a veteran in the automobile and bicycle business. He was formerly purchasing agent for E. C. Stearns & Co., of Syracuse, and later became secretary of the Stearns Canadian company, finally going to Australia as manager for the Canada Cycle & Motor Company.

Howard M. Post has accepted the position of advertising manager with the Quincy, Manchester, Sargent Company, manufacturers of railroad appliances, who have offices in Chicago and New York, with factories at Chicago Heights, Ill., Milwaukee, Wis., and Plainfield, N. J. Mr. Post originally fitted himself for a telephone engineer and held a position as telephone switchboard installer with the Western Electric Company, of Chicago.

Frank P. Libbey, the Salt Lake City representative of the Lozier Motor Company, has formed a connection with the Consolidated Wagon & Machine Company, of Salt Lake, and the Lozier will hereafter be represented in the intermountain district by this concern, which has branch houses throughout Utah and Idaho. The company is one of the solid financial institutions of Salt Lake, the directorate being composed of many high officials of the Mormon Church, who have shown a keen interest in automobiles for some time past.

NEW TRADE PUBLICATIONS.

Hooper Bros. & Darlington, Westchester, Pa., have sent out a 1907 tear-off calendar on which they present their fine wagon and carriage wheels and announce their different types of wood hub wheels.

An interesting booklet is just at hand from the National Carbon Company, Cleveland, Ohio, on "How to adjust a spark coil." Instructions are complete and concise, and doubtless numberless automobilists will be glad to avail themselves of the offer of the company to send a free copy on request.

"A little book which tells in narrative style the story of its conception and perfection," is the appropriate introduction to the booklet issued by the Craig-Toledo Motor Co., Toledo, Ohio. It is interesting reading and tells the various experiences which the Craig-Toledo car went through before it was considered good enough to put before the public.

Information likely to be of use to other than the automobile novice is contained in the brochure issued by the Albert Champion Company on Gianoli high-tension magnetos. A detailed and illustrated description of the magneto is given, followed by a treatise on adjustment and care of the ignition system, and useful hints on how to remedy minor defects.

A complete description, with numerous illustrations, of the Hawthorne Works, of the Western Electric Company, is given in the booklet just issued by that firm. External views of the works and a series of half-tones of the machine shops give some idea of the magnitude of the Western Electric Company's equipment.

Attractively presented in blue and gold, the catalogue of the Mayo Radiator Company, of New Haven, Conn., gives illustrations of the various types of radiators produced by that firm for the 1907 season. The line is a complete one, and amongst the radiators presented are those of several important American automobile firms regularly fitted with the Mayo product.

The National Sales Corporation, 296 Broadway, New York, has prepared a sheet of electros for the use of jobbers, illustrating Connecticut coils, "Soot-Proof" plugs, Royal batteries, Peugeot chains and rims, "P. D. Q." tire repair plugs, etc. The cuts are made in several sizes in order to meet the requirements of the different jobbers who may issue a large or small catalogue.

Patterson, Gotfried & Hunter, Limited, of 146-150 Centre street, New York City, have issued a new catalogue to meet a persistent demand on the part of automobilists needing tools and supplies. Articles of interest only to jobbers or blacksmiths have been kept out of the new publication, but all tools likely to be needed by the private automobilist or the garage proprietor are described by text and cuts and are priced.

A most attractive catalogue is that of the 1907 Columbia gasoline cars, which is now being distributed by the Electric Vehicle Company. It is a book of forty pages, bound in an exceedingly handsome cover done in gold tracery. The catalogue is printed throughout in two colors and contains beautifully executed half-tones of the separate models

and their component parts. One of the most striking features is an "X-ray," or shadowgraph, reproduction of the 24-horsepower touring car. This reproduction is 18 by 12 inches in size and is folded into the center of the book.

Climax Electrical Commutator.—Ignition defects are probably responsible for nine-tenths of the troubles experienced by automobilists. To remedy this A. B. Black, 21 South Market street, Boston, Mass., has produced a new timer, known as the Climax Electrical Commutator, which it is claimed will

CLIMAX ELECTRICAL COMMUTATOR.

give perfectly synchronized ignition. Each cylinder gets its spark at the exact point, keeping them in perfect time, making each do the same amount of work, no matter whether there are two, four or six cylinders, and when once adjusted needs no further attention.

A Useful Tire Tool.—To overcome the difficulties experienced in mounting and removing clincher tires, a useful tool known as the "Ever Ready," handled by the Auto Improvement Co., 316 Hudson street, New York, has just been brought out. With this instrument

EVER READY TIRE TOOL.

tire removal presents no more difficulty than does the cranking of the engine. The tool is readily inserted under the outer shoe, without any danger of injuring the inner tube, and the tire removed by an easy rotary motion. In two minutes the tire can be removed or put on.

THE AUTOMOBILE

VOL. XVI.

NEW YORK—THURSDAY, JANUARY 24, 1907—CHICAGO

No. 4

A SHOW THAT HAS MADE AUTO HISTORY

WITH a final triumphal flourish that was in keeping with its undisputed reign throughout the week, that not even the most unpropitious of weather could diminish, the Madison Square Garden show came to a close on Saturday night last. It passed, but not into oblivion, for it will long be remembered as marking a standard of achievement only made possible by the accumulated experience of the seven years of effort in the

same direction that had preceded it. Judging it from the one criterion that has served as a basis upon which to decide the success of every show that has gone before—that of attendance—it is not difficult to estimate how greatly this one has surpassed the preceding Garden exhibitions. Interest in this feature of it was doubled owing to the inauguration of the experiment of charging a double admission on two days of the

THE MUCH ADMIRER "BRIDAL CAR"—AN ISOTTA FRASCHINI—A LADIES' FAVORITE AT THE RECENT GARDEN SHOW.

AN EXHIBIT OF FUNDAMENTALS THAT WAS FETCHING.

week. But neither this nor the added damper of extremely inclement weather appeared to have any appreciable effect, either on the attendance of the days in question, nor of the aggregate for the week. Last year's attendance for the week rolled up into figures of such magnitude that it was hardly thought possible that they would be greatly surpassed for several years to come, yet it is confidently estimated that the increase during the past week over that of its predecessor of a year ago ranges all the way from 10 to 20 per cent.

Models Exhibited Represented Regular Stock.

As for the business done—not even the time-honored “all sold out” begins to express it. A few years ago all the salesmen at the stands were at pains to assure the inquiring visitor that they had not a car to sell when his object in asking was known; in many instances their factories had closed contracts for every car they could possibly turn out during the delivery season long before they ever came to the show. They were only there to let the public see what they could do in the way of building cars and—they were not altogether adverse to booking a few more orders. The saying has long since passed into the limbo of other forgotten things, though seldom before has the maker come to the show with so much of his output sold in advance as was the case during the past week. The business of rushing work night and day for several weeks prior to the show in order to be able to ship a few models at the last moment is another thing of the past. The great majority of the cars that were rolled into place on the Saturday previous were as ready for exhibition as the decorations were to receive them, and both had been prepared with plenty of time to spare. With the exception of the polished chassis, which has come to represent a fixture, the cars staged at last week's show were not the laboriously prepared samples of other days. In but few instances did they lack anything but a supply of fuel, lubricating oil and batteries to make them ready for the road. Nor were they the first of their kind—the advance agents of their line for the coming season; far from it in numerous instances, as 1907 models galore have been in the hands of purchasers since last summer.

The Placing of Orders More or Less a Formality.

As to the actual amount of business done, that is something that is next to impossible to estimate with any degree of accuracy. That it has been large, both in individual instances as well as in the aggregate, and that it has exceeded by a substantial margin the amount done during any previous show week, may be taken for granted. A few years ago the makers generally were very keen about the business to be done at the show. It was really the opening shot of the season and was depended upon in very large measure to provide a book full of

orders to keep the factory busy during the period intervening between the closing of the show and the coming of mild weather. The maker is probably no less keen about booking orders now than he ever was; but there has been a very radical change in this respect during the past few years, and its influence was never more apparent than during the show just closed. The show is no longer looked upon to the same extent as a market place, despite the fact that more actual orders were probably booked during the week in question than during the first three or four shows combined. But in all probability the same makers would have received those orders anyway—in other words, the show has come to be more or less of a formality where a large majority of autoists are concerned, though it still forms a sort of initiation for the constantly increasing number of recruits who find in the shining array of cars of all types an attraction too strong to be successfully resisted.

Technical Education of Buyers Is Noticeable.

But in the crowd that filled the aisles and swarmed over every booth for ten to twelve hours a day and every day the doors were open, it was harder than ever to spot the novice. If there be any one far-reaching effect for which the automobile may be said to be entirely responsible it is that of education. The curriculum has been diversified, but in no other respect is the effect so marked as where the mechanics of the car are concerned. People who had about as much idea of the technical requirements of the automobile as they did of the infinitesimal interim now talk learnedly of cylinder capacities and dimensions with regard to the horsepower as if they had been brought up on it, where formerly hardly one in a hundred could distinguish the transmission from the differential and had utterly no conception of the clutch or the reason for its necessity. To realize the extent to which this education has been carried on, or more properly speaking, the number of people who may be said to represent the automobiling public, it was only necessary to join the interested group invariably to be found surrounding one of the many polished chassis shown and listen to

POPE-TOLEDO DASH SHOWING FOLDING WINDSHIELD.

the string of questions fired at the salesman, who was doing his best to elucidate matters to an audience of varying degrees of automobile education. Where formerly there would have been but one mechanical "sharp" as the nucleus of such a group, half a dozen were in evidence. To quote a prominent maker, "the public now wants to know so much that the average inquirer is far from satisfied with the maker's statement that his motor deliver 25 to 30 horsepower. He wants to know the why and how of it, and what is more, he wants particularly to know how it is that blank's motor of smaller dimensions delivers more power, or why its builder says it does." And this is more than ever true of the power behind the checkbook, the women of the family. True enough, there were just as many who tried to give a horse-show flavor to things by exhibiting their elaborate toilets from the most conspicuous places; others whose only idea was to pose in the front seat of a car, and still others whose sole idea of a machine's merit was gained by jumping up and down a few times on the seats to test the

this capacity is still far greater than the supply, and the "mechanical man" or the "factory man" is as much a refuge in case of need as ever. But the fact that must have struck the observant eye, familiar with what has gone before, in the most forcible manner, was the close approach to standardization that has been reached, whether the cars were considered in the aggregate or in groups outlined by price limitations. In either case a composite might readily be made, including cars of both foreign and domestic origin, that would approximate so closely to a standard type of automobile as to make it difficult at first sight to note how the individual features of many of the varying forms of construction had been blended to form the whole. This was particularly noticeable when a comparison was made of the principal features of construction as represented by the leading foreign and American-built cars, in many cases a comparatively unimportant detail here and there not apparent to any but the trained eye, marking the only visible difference.

FOURTH AVENUE END OF MADISON SQUARE GARDEN, WHERE THE DEMONSTRATING CARS WERE LINED UP AWAITING ORDERS.

resiliency of its upholstery while comparing the blending of colors in its exterior finish. This is a contingent that will probably always be in evidence to about the same extent, but that there has been an amazing increase in the number of women who can talk motors, gears and drives intelligently was something that could not fail to impress the observant and it put the salesmen on their mettle more than ever, for if it is humiliating to have a well-rehearsed story turned awry by a man and its teller stranded in a mass of contradictory statements, how much more so is it when done by a woman?

Close Approach to Standardization Was Noticeable.

Education has also overtaken the salesman in a great many instances, but there are not lacking those in which he is the same impossible being that he always was. "Four-cylinder vertical motor in front, 40-horsepower, multiple disc clutch, selective transmission, shaft drive" is still the burden of his song that has only changed in detail with the march of improvement. The only explanation is that the industry has grown so exceedingly fast that the demand for technically informed men in

Quick Work Signaled the Dismantling at the Finish.

Just as the show with all its variegated paraphernalia and trappings swooped down on the Garden and occupied it to the last niche, with the same celerity it packed up and decamped after the most successful week it has ever enjoyed. Within less than twenty-four hours after the closing hour Saturday night, the floors and balconies were again as empty and the walls as bare as is their usual condition. A large number of the exhibits complete were sent direct to special freight trains that were awaiting their arrival. Elaborate plans had been made for the quick transfer of the exhibits to the Chicago show, and before the New York show had grown cold they were on their way to the Windy City in special trains which left for the West Monday morning.

The Turin (Italy) Automobile Club is organizing a six days' touring contest for the week of June 18-23. This contest will be run in lieu of the hill-climbing contest up Mont Cenis, which was suppressed by the authorities.

CHICAGO'S DECORATIVE SCHEME.

Not to be outdone by its eastern rival, Chicago has been putting forth strenuous efforts for the past two or three months in anticipation of revealing as elaborate and complete an effort in the form of an automobile show as has ever been thrown open to the public. Accustomed to doing things on a vast scale, it has made preparations to house the automobile in a setting calculated to surpass anything hitherto attempted where beauty and elaborateness of decoration are concerned, as well as to uphold its name for record-breaking achievements. In short, Chicago's show is to eclipse all former efforts, whether of the home or foreign talent; it is to be the largest ever held, whether in this or any other country. As was the case last year, every available square inch of space afforded by both the Coliseum and the First Regiment Armory, diagonally backing it on Michigan avenue, will be utilized. There will be a greater number of exhibitors, both of cars and accessories, than has ever participated in any American show—more than 300, in fact—and the problem that has confronted the management has been how to accommodate all that desired to have space. No one thing accentuates the magnitude of the show as a whole, so much as the fact that of the total number of exhibitors, 102 will display complete cars—the greatest number that has ever been brought together on a similar occasion in this country. Added to these there will be 190 exhibits of accessories of every conceivable nature and eight of motorcycles.

MERCURY,

The fleet-footed messenger of the gods, will be a prominent factor in the Chicago Show decorations.

The combined buildings contain more than 80,000 square feet of available space, which is said to be twenty-five per cent. greater than the total floor space occupied by any automobile show ever held outside of Chicago, not even excepting that of the St. Louis Exposition of two years ago. Further details of the plan of decoration adopted for the main floor of the Coliseum serve to give a better idea of the elaborate scale on which this is to be carried out than the advance announcements published some time previous. As an instance of this, there may be cited the fact that the arches which will form the dominating feature of the decorative scheme will range from 3 to 5 feet 6 inches in height and from 14 to 22 feet in length. The smaller arches have been designed with a view to the ornamentation of the accessory sections of the show, while the larger ones will be employed in the sections devoted to cars. One of the accompanying photographs illustrates a section of one of the smaller arches in question. The material employed is staff, while the finish is an old ivory shade. Another of the illustrations shows the square cap which will serve as the ground piece for the vertical columns. Wherever one looks the figure of Mercury will be in evidence. As the deity symbolical of one of the chief attributes of the automobile—that of

speed—his figure will dominate every stand. Two of these figures will be placed on a low pedestal in the foreground of each exhibit, one of them being utilized to bear a brass sign carrying the name of the car shown at each space. The principal sign will be readily distinguishable at each of the spaces, and they will be of raised letters in white and gold, on scarlet background, topped off by a long narrow piece of ornamental staff forming a cap for the sign, and above this will be the arches referred to. Huge quantities of staff will be employed in a variety of forms.

A. M. C. M. A. PLANS.

Although no definite announcement was made, it is understood that at the recent meeting of its committee of management the American Motor Car Manufacturers' Association decided upon some important plans for next winter's automobile show. The report that the Grand Central Palace affair of last month permitted a return to exhibitors of \$45,493 was received with much favor, and this might be expected, especially when it is known that members of the association received an additional 20 per cent. dividend.

The plan of having a central organization for activity in good roads was recommended for an open discussion at the annual meeting to be held in Chicago, when some action will be taken with a view of supporting and working with the National Association of Automobile Manufacturers on the plans recently outlined, which have for their purposes a centralization of all those organizations interested in securing good roads, so as to have concerted action along definite lines. A coalition of interests with this end in view must result in incalculable benefit to the industry as a whole, and no effort will be spared by the American Motor

CAPS SURMOUNTING THE COLUMNS.

Car Manufacturers' Association to make the movement a pronounced success.

There are now forty prominent manufacturers of motor cars in the organization, which has been in existence less than two years. The annual meeting of the organization will be held on February 7, during the Chicago automobile show.

Two pounds to the horsepower is said to be the weight of latest Santos-Dumont aerial motor.

HALF-SECTION CHICAGO SHOW DECORATION, SHOWING BAS RELIEF.

MECHANICAL BRANCH A. L. A. M. OPEN SESSION

METAL Alloys Applied to the Various Parts of Automobiles" was the subject for discussion at the first day's meeting of the Mechanical Branch of the Association of Licensed Automobile Manufacturers, while the subject of gears and magnetos occupied the second day's session. Breaking away from the precedent hitherto adhered to of making these meetings something in the nature of star chamber proceedings, representatives of both special interests were invited to be present and take part in the discussion. Representing the ignition end, there were present: Robert Bosch, head of the American house handling the Simms-Bosch magneto; Messrs. Remy, of the Remy Electric Company; Forein, of the Holtzer Cabot Company; Holly, of Holly Brothers; Hull, of the Polyphase Ignition System Company; Leon Rubay; Hart, of C. F. Splitdorf; Herz, of the Herz Manufacturing Company, besides representatives of the Heinze Electric Co., and Lavellette & Company, owners of the American patents on the Eisemann magnetos. From the gear-making interests there were present Messrs. Beall, of Brown & Sharp; Burgess, of the Boston Gear Works; Fellows, of the Fellows Gear Company; Cameron, of Gould & Eberhart, Jr.; and Gleason, of the Gleason Works.

To aid in bringing out the points that it was desired to emphasize, every one of the manufacturers of magnetos provided a sample of his machine, which was shown both complete

and dismantled. The chief point dwelt upon was the necessity of standardization in order that any magneto on the market might be made readily applicable to any car without the necessity of any machine work. Another important feature of the discussion was as to the best position for the magneto—whether it should form an integral part of the motor itself or whether it should be considered an accessory and placed on the dashboard.

On the subject of gears the questions as to the value of different types, such as spur, bevel, helical and the like, was taken up in connection with the feature of the gears themselves, such as the proper length, width and pitch of the teeth, their general conformation and the relative efficiency in practice of the various types. The matter of the most suitable methods of cutting gear-teeth of different characters was also taken up and discussed at length. The members present were Hiram Maxim, Electric Vehicle Co.; Elwood Haynes, Haynes Auto Company; S. H. Cutler, Knox Auto Company; J. H. Jones and A. L. Riker, The Locomobile Company; Russell Huff, Packard Motor Car Company; M. C. Bernin, Lozier Motor Co.; G. J. King, Northern Motor Car Co.; David Ferguson, George N. Pierce Company; L. D. Hubell, Pope Motor Car Company; S. N. Sanborn, Alden, Sanborn & Company; H. E. Coffin, E. R. Thomas Detroit Company; Ralph Morgan, E. R. Thomas Motor Company, and F. D. Howe, Waltham Manufacturing Company.

SOCIETY OF AUTOMOBILE ENGINEERS' ANNUAL MEETING

ONE of the chief events of show week just past was the second annual meeting and dinner of the Society of Automobile Engineers, which was held at the New Grand, Thursday afternoon and evening, the dinner, at which forty-four of the members were present, being held between the two sessions. The afternoon session was opened by the reading of a paper by Thomas J. Fay, the subject originally assigned him having been "Some Features of Construction." Mr. Fay explained that his idea had been to talk about some features of construction on well-known cars that he did not like, but as this would savor too much of public disparagement, he had taken up the subject of materials instead, and gave a very interesting talk on steels and aluminum for automobile work, which aroused general discussion and brought out many valuable points. He was followed by Thomas J. White, who read a carefully prepared paper on alcohol, which, in view of the present situation where this fuel is concerned, was of unusual interest. In the discussion that followed Joe Tracy gave his experience in the use of this fuel on his recent test run, and numerous facts not commonly known were brought to light.

After the dinner the evening session was opened by the reading of a paper entitled "Some Facts Pertaining to Electric Ignition," by Henri G. Chatain. The paper was based upon numerous test experiments made with a high tension Simms-Bosch magneto, as well as on a large number of induction coils of both American and foreign makes. The results were illustrated by oscillographs thrown on the screen by a stereopticon. A great many slides were used, graphically showing every phase of current and potential change during the revolution of the inductor, and accurately establishing the electric range of the latter throughout which the current can be advantageously used for ignition, as well as the corresponding relation this bears to the crankshaft revolution. A large number of slides were also used to illustrate the differing characteristics of a great many induction coils of well-known makes, and voluminous data pertaining to them was given in connection with the result of each experiment, making the

paper, as a whole, one of the most valuable of the kind that has been prepared in this country. Mr. Chatain said, by way of introductory, that he had been led to investigate the subject by reason of the fact that the only information extant as to the requirements was that a "hot" spark or a "fat" spark was what was needed, but that, after a great deal of experimenting he had been unable to exactly determine the nature of these characteristics, particularly a "fat" spark, a statement that aroused considerable merriment. He was followed by Henry Hess, of the Hess-Bright Company, who read a paper on "Change Gears and Their Journals," which was also profusely illustrated with the aid of the stereopticon, showing a large number of change-speed gear boxes of standard makes, as well as a great amount of graphic data in connection therewith. He also explained the requirements necessary where the load was simply radial or thrust, or where it was of both natures and the sizes of ball bearings to fit each case, beside citing some of the causes for their failure, chief among which was the prevailing impression that a bearing of this type does not require any lubrication, and that there is no particular necessity for protecting it from dirt. Mr. Hess's paper was interspersed with a number of witty sallies.

Owing to the time required for the presentation of the illustrated papers, there was no opportunity for discussion, and for the same reason the election of officers for the coming year had to be postponed, a resolution continuing the present incumbents in office during the interim being passed unanimously. Among those present were A. L. Riker, E. T. Birdsall, H. M. Swetland, H. L. Pope, Joe Tracy, Henry Hess, Thomas J. White, Henri G. Chatain, Thomas J. Fay, F. D. Russell, W. G. Wall, Paul L. Snutsel, C. E. Reddig, R. D. McDonald, Mr. Heckel, A. C. Schultz, J. G. Perrin, G. E. Franquist, A. M. Holcomb, Charles F. Barrett, R. M. Beck, Lindley D. Hubbell, L. H. de L. Espel, Mr. Miller, Herbert L. Towle, R. B. Wasson, H. F. Donaldson, Mr. Acker, J. N. Ellsworth, H. F. Barker, L. T. Gibbs, H. P. Mooras, George O. Gridley, Mr. Conover, C. B. Hayward and Harold H. Brown.

N. A. A. M. ELECT OFFICERS AND REVIEW THE YEAR

RESPONDING to the call for the annual meeting of the executive committee of the National Association of Automobile Manufacturers, Inc., fourteen of the fifteen members gathered at the Victoria Hotel in this city on Thursday last. The chief business before the meeting was the election of five members of the committee to serve three years. The balloting resulted in the election of Thomas Henderson, Winton Motor Carriage Co.; Benjamin Briscoe, Maxwell-Briscoe Motor Co.; M. J. Budlong,

ALBERT L. POPE,

Vice-president Pope Mfg. Co.

Elected President of the National Association of Automobile Manufacturers.

Electric Vehicle Co., and E. H. Cutler, Knox Automobile Co., who were candidates for re-election, and William Mitchell Lewis, Mitchell Motor Car Co., who had not previously served on the executive committee. After the annual meeting of the association, which was sandwiched in between the two meetings of the executive committee, the newly elected committee convened for the purpose of electing officers for the association. The balloting resulted as follows: Albert L. Pope, Pope Manufacturing Co., president; S. D. Waldon, Packard Motor Car Co., first vice-president; Thomas Henderson, Winton Motor Carriage Co., second vice-president; William E. Metzger, Cadillac Motor Car Co., third vice-president; W. R. Innes, Studebaker Automobile Co., treasurer, and L. H. Kittridge, Peerless Motor Car Co., secretary. S. A. Miles continues as general manager.

At the first meeting of the executive committee L. E. Burr was elected to represent the Woods Motor Vehicle Co., in place of J. Wesley Allison, and E. P. Chalfant to represent the Waltham Manufacturing Co., in place of F. E. Bradley. A resolution was adopted exempting the cars which took part in the elimination trials and the Vanderbilt race itself from the provision of the rule which prohibits manufacturers from exhibiting cars at local shows. The good roads committee announced that the work of forming a national association had progressed to such an extent that a substantial appropriation by the N. A. A. M. seemed desirable, and suggested that \$5,000 be set aside for the purpose, to be used only on condition that twice that sum be raised by the other associations interested. The executive committee indorsed the recommendation, but referred it to the new executive committee for definite action. The contest committee reported that it had prepared a set of rules for a contest, which were ordered printed and a copy transmitted to each member of the executive committee, pending a full discussion at a later meeting. In accordance with an arrangement entered into with the Motor and Accessory Manufacturers, Inc., under which it is intended that eventually the membership of the national association shall consist exclusively of manufacturers of automobiles, all makers of parts and accessories being referred to the newer organization, the resignations of the following associate members were accepted: Motsinger Device Manufacturing Co., National Carbon Co., Brown-Lipe Gear Co., Baldwin Chain and Manufacturing Co., Fisk Rubber Co., Whitlock Coil Pipe Co., Rose Manufacturing Co., Electric Storage Battery Co., Twentieth Century Manufacturing Co., Diamond Rubber Co., Badger Brass Manufacturing Co., G & J Tire Co., Hartford Rubber Works Co., Shelby Steel Tube Co., Veeder Manufacturing Co., R. E. Dietz

Co., Dayton Electric Manufacturing Co., B. F. Goodrich Co., and the Goodyear Tire and Rubber Co.

This meeting was followed by the annual meeting of the association, at which forty-two members were in attendance. The report of President E. H. Cutler dealt exhaustively with the work of the past year. Commenting on the progress of events, Mr. Cutler said:

"It is a source of satisfaction to your president to be able to make, with unqualified pleasure, the statement that the development of the automobile industry during the past year has been fully in keeping with the optimistic view of the outlook as it appeared a year ago, and that the favorable conditions that prevailed have continued, and seem likely to continue, among those manufacturers who conduct their affairs on sound commercial lines. It is gratifying to note that among those concerns which practically everyone regards as the leaders of the industry (nearly all of whom are included in the membership of this association) there has been a disposition toward reasonable conservatism, and no disposition to force upon the market a greater number of cars than the market will readily absorb. In the quality of cars there has, of course, been marked improvement. So long as these two features go hand in hand there is little doubt about the continuance of that prosperity with which the automobile industry has heretofore been blessed.

"It has been the policy of the executive committee of this association, representing, as the members believe, the truly national organization of the United States, to adhere firmly to the conservative principles on which the association has been successfully conducted for the last seven years. It has been their endeavor to build up and help to perpetuate an association whose membership is regarded by the public as an indication of the stability of the member, and which, therefore, shall have among its members none but those concerns which have proved beyond question that they are deserving of the public's confidence.

"The result of this policy has already been made evident. During the early days of the organization, when its organizers were anxious to secure a large membership, little attention was paid to the standing of the applicant. Indeed, the condition of the industry at that time was such that there were few manufacturers old enough to have established themselves very firmly in the public's confidence. Some of the members who were admitted at that time have since fallen by the wayside, but it is a source of gratification that the policy adopted in later years has built up a membership among concerns so reliable that failures among them are practically unknown."

The report commented at considerable length on the efforts of the association to prevent unreasonable legislation, and showed that the efforts had been eminently successful. The association's test case in New Jersey is still proceeding. The case appears on its face to demand that no license at all shall be required, but the association would be perfectly satisfied with the establishment of the principle that one license must be recognized in all parts of the country. The test was commenced in 1905, and has been carried through the Magistrate's Court, the Court of Common Pleas and the Supreme Court of New Jersey. It has now reached the Court of Errors and Appeals, and will, in due course, be carried to the United States Supreme Court. The report also presented many interesting details relative to the good roads movement. It will be printed and forwarded to the members of the association in due course. The treasurer's report showed the financial condition of the association to be eminently satisfactory, the balance in the hands of the treasurer being considerably greater than at the same period last year, despite somewhat heavy outlays during the interim. This will be largely increased by the Chicago show. No rebate will be given exhibitors, a reduction in space rates being made instead.

HOTCHKISS, OF BUFFALO, TAKES A. A. A. HELM

MUCH is expected of the new administration of the American Automobile Association. William H. Hotchkiss was an able president of the Automobile Club of Buffalo, and under his leadership the New York State Automobile Association became strong and energetic. Now the man from Buffalo has taken the A. A. A. helm, and the effects of his early occupancy of the office are apparent.

W. H. HOTCHKISS,
The New A. A. A. President.

The concluding session of the old board of directors and the first meeting of the succeeding board were held at the new clubhouse of the Automobile Club of America last Thursday and Friday. The organization being a New Jersey corporation, it was necessary to hold a proxy meeting of stockholders at East Orange, N. J., on Friday morning.

Under the influence of the magnetic enthusiasm of the new president extensive and far-reaching plans were outlined for the immediate future. Charles Thaddeus Terry is to head the new legislative board; Robert P. Hooper, of the Automobile Club of Germantown, will retain the chairmanship of the good roads board, and it has been known all along that Mr. Hotchkiss particularly desired Jefferson deMont Thompson to continue as racing board chairman.

The other chairmanships will be announced very shortly, as the new president does not desire to lose any time in getting under high speed. This is apparent by the quick completion and announcing of the executive committee upon which will devolve much of the work hereafter, owing to the constitutional change whereby the board of directors will only meet in March, September, and December. President Hotchkiss names as the four additional members of this committee William K. Vanderbilt, Jr., Jefferson deMont Thompson, A. G. Batchelder, and Sidney S. Gorham. The president, first vice-president, and treasurer are members by reason of their offices.

Neither Mr. Farson, the retiring president, nor Mr. Gorham, the secretary, sought a continuance in office. Mr. Elliott, the new secretary, is especially fitted for his task because of an uninterrupted occupancy of the New York State Automobile Association secretaryship. Herewith is the new official roster:

Officers of the A. A. A. for 1907.

- President—William H. Hotchkiss, Automobile Club of Buffalo.
- First Vice-President—Lewis R. Speare, Bay State Automobile Association.
- Second Vice-President—Asa Paine, Florida East Coast Automobile Association.
- Third Vice-President—Ira M. Cobe, Chicago Automobile Club.
- Treasurer—George E. Farrington, Automobile Club of New Jersey.
- Secretary—Fred H. Elliott, Syracuse Automobile Club.
- Executive Committee—William H. Hotchkiss, Lewis R. Speare, William K. Vanderbilt, Jr., Jefferson deMont Thompson, A. G. Batchelder, Sidney S. Gorham, George E. Farrington.

Board of Directors.

- New York State Association—W. H. Hotchkiss, A. C., of Buffalo; Oliver A. Quayle, Albany A. C.; Colgate Hoyt, A. C. A.; W. K. Vanderbilt, Jr., A. C. A.; Jefferson deMont Thompson, A. C. A.; A. R. Pardington, Brooklyn, N. Y.; S. B. Stevens, New York Motor Club; A. G. Batchelder, New York Motor Club; N. M. Pierce, Binghamton A. C.; H. S. Woodworth, Rochester A. C.; F. B. Hower, A. C. of Buffalo.
- Massachusetts State Association—Elliott C. Lee, Massachusetts A. C.; Lewis R. Speare, Bay State A. A.; J. P. Coghlin, Worcester

- A. C.; S. L. Haynes, A. C. of Springfield; G. E. Bliss, Maiden A. C.; W. H. Chase, Wachussetts A. C.

- New Jersey State Association—Frederick R. Pratt, N. J. Automobile and Motor Club; George A. Post, North Jersey A. C.; J. H. Edwards, A. C. of Hudson County; George E. Farrington, New Jersey A. C.; W. E. Edge, Atlantic City A. C.; K. G. Roebbling, Mercer County A. C.

- Illinois State Association—John Farson, Chicago A. C.; Ira M. Cobe, Chicago A. C.; Sidney S. Gorham, Chicago A. C.; George W. Ehrhart, Decatur A. C.; S. P. Irwin, Bloomington A. C.

- Ohio State Association—F. T. Sholes, Cleveland A. C.; Windsor T. White, Cleveland A. C.; Val. Duttonhoefer, Jr., A. C. of Cincinnati.

- California—Dr. Milbank Johnson, A. C. of Southern California.
- Connecticut—J. Howard Morse, Hartford A. C.; George M. Sanders, New Britain A. C.

- Florida—Asa Paine, Florida East Coast A. A.

- Georgia—H. J. Lamar, Macon A. C.

- Louisiana—Albert Mackie, A. C. of New Orleans.

- Maryland—W. S. Belding, A. C. of Maryland; Osborne I. Yellott, A. C. of Maryland.

- Michigan—Paul H. Deming, A. C. of Detroit; D. Emmet Welch, Grand Rapids A. C.

- Minnesota—Frank M. Joyce, Minneapolis A. C.; F. A. Wood, St. Paul A. C.

- Missouri—Roy F. Britton, A. C. of St. Louis.

- Pennsylvania—George H. Smith, Quaker City Motor Club; Robert P. Hooper, A. C. of Germantown; Phillip S. Flnn, Pittsburg A. C.

- Rhode Island—William P. Mather, Rhode Island A. C.; R. L. Lippitt, Rhode Island A. C.

- Texas—E. H. R. Green, Dallas A. C.; H. S. Crawford, San Antonio A. C.

- Wisconsin—James T. Drought, Milwaukee A. C.

Inaugural Address of President Hotchkiss.

The inaugural address of President William H. Hotchkiss is a most interesting document, containing much worth careful reading, and digestion. It is herewith given in its entirety:

In assuming the executive office of the association, I deem it proper to lay before you certain matters of present importance to American motorists.

A Truly National Body.—The association is now in its fifth year. It comprises 5 State associations, 23 clubs and organizations not affiliated with State bodies, and 267 individual members. The State associations are made up of 48 clubs, having 7,035 members. The grand total of membership is 8,857, scattered over all the States and federal districts, except Oklahoma. It is the only truly national organization devoted to the pleasure and sport of motoring. It is still in its infancy, with its work hardly organized and its functions and powers little appreciated. Those who are charged with its management, therefore, should approach their duties with a proper sense of responsibility. On their work may depend the making or the marring of a cause vital to but thousands now, but soon to be that of the tens, nay the hundreds, of thousands of the coming horseless age.

Merely a Central Committee.—Motorists are chiefly interested in good roads, fair laws and ordinances, and in a proper observance and enforcement of them. Thus, the functions of government with which they are most concerned are the police and taxing powers; both functions of the State, rather than of the nation. Their interests thus being local, the work to be done in their behalf must be done largely in their home communities.

Hence, this association did most wisely when, at a recent meeting of this board, it modified its by-laws in ways tending to encourage the organization of affiliated State associations wherever motorists are sufficiently numerous or interested. This step should be followed by a comprehensive plan whereby the active control of movements toward better highways and fair local legislation shall be vested in such State associations; the national body as to these matters becoming merely a central advisory committee. Such

FRED H. ELLIOTT,
Elected Secretary of the A. A. A.

a plan would, of course, leave with the association proper the control of all legislation and activities national in their scope. To this end I urge the early adoption by the board or its executive committee of a statement defining the limits and the powers of the State and national bodies; this that neither may trench on the sphere of the other, and all work harmoniously for the common cause.

Federal Legislation.—Our American system of independent federated States makes any national legislative program difficult. Motor vehicle laws now in force differ widely in their provisions as to the rate of speed, the means of identification, the penalties for violations, and the fees or taxes paid. Some States are liberal; others, by leaving these matters to their cities and towns, almost prescriptive. In present conditions I mean the newness of the motor vehicle as a means of transportation and the prejudice created by a few heedless or brutal drivers—these differences will for a time continue, and, perhaps, increase. Activity by State associations will, however, hasten the inevitable day when the only local regulation as to speed will be that a motorist shall not drive at a greater rate than is reasonable or proper, having regard to the traffic on and the condition of the highway at the time. Whether such consummation shall be reached before motor vehicles become more numerous on the streets and roads than horse-drawn vehicles is a question. That, perhaps, depends more than we think on how sanely we and our neighbors now drive. But, the day will come, and before the closing of the century's second decade!

Of late, however, there has sprung up in some States a tendency which must be checked—a tendency to treat the non-resident motorists as good picking, a tendency, in short, to tax. Several States permit the non-resident owner of a motor vehicle to operate at within their boundaries without additional registration, some even without limitation as to time, always provided the motorist observes the police regulations there in force. In such States the horse-drawn and the motor-driven vehicles are, so far as possible, on an equal footing, as they should be. Elsewhere, however, desire for revenue has led to a State toll tax, in the shape of a license or registration fee. The amount exacted is not yet large, but the scheme is yet young. Legislators who bring in bills enforcing new ways of getting revenue, especially from the so-called privileged classes, are, perforce, popular with their constituencies. The cloud no larger than a man's hand may soon darken the sky. Immediate action is essential. The call for it is already strident and country-wide. What shall that action be?

The demand is for federal regulation of the motor vehicle as an agency of commerce and intercourse. How far such demand is reasonable and its realization possible have of late been much debated. It should early have attention from the association's legislative board, and should be pressed to a conclusion in the next Congress.

Clearly, a tax on a non-resident's property while temporarily in the taxing State, such property presumably being already taxed in the State of the owner's residence, might, because contrary to general law, be difficult of enforcement. Hence, a greedy State attempts to evade by requiring non-resident owners or operators to register for purposes of identification, and furnishes those registered with numbers, seals or licenses, all on payment of a so-called fee. The sum total of these fees creates a fund much in excess of the State's outgo, which, with some unction, the State devotes to the maintenance of its improved highways!

Now, it is not the function of this association, as such, to quarrel with the lawmakers of States, who, in an exercise of the police power, pass registration laws affecting resident motorists and devote the surplus revenue thus obtained to the up-keep of highways. That matter is one for each State association to handle as best it may. If there is thereby no double taxation—which there may be—and if registration for identification purposes is, in present conditions, a reasonable exercise of the police power—which it probably is—then there can be no just complaint.

But when a motorist thus tagged and taxed chooses to drive his car into or through another State, it may well be urged that both the requirement of additional registration and the exaction of a fee or tax therefor is unlawful, because an unreasonable exercise of the police power. If thus unlawful, it is also unconstitutional, because an unjust and unwarranted interference with the commerce and intercourse between the States. The State of the motorist's residence has provided means for his identification in case he violates law or does injury. No other State should be permitted to do it over again.

Without further argument at this time, however, the following considerations are suggested, to the end that discussion may be stimulated and the work of the legislative board and the corresponding local committees be somewhat guided:

(1) It is within the police power reserved solely to the State by the fathers of our government to regulate the use of the State's highways by citizens of all the States, provided such regulation is reasonable, and does not interfere with free interstate intercourse. Thus, Congress has perhaps now no power to pass a law fixing rates of speed or providing penalties.

(2) While laws enforcing the police power must be uniform in their operation, conditions may exist which permit different laws for different classes of persons. Thus, in present conditions, the States probably have power to pass motor vehicle laws requiring registration and regulation speed.

(3) Identification being, however, accomplished by the registration features of the law of a motorist's residence, a new identification required by the law of another State is probably an unreasonable exercise of the police power and, if so, unlawful.

(4) The decisions of the Supreme Court and the tendencies of public opinion warranting the conclusion that the word "commerce" in Article I, Paragraph 8, of the Federal constitution means not only business intercourse, but also intercommunication in a broad sense, Congress probably has power to pass a law, for instance, whereby a motorist may certify to some department or bureau of the national government that his motor vehicle is duly registered in his own State and that it is his bona fide intention to use such vehicle in a State or States other than that of his residence, and that, thereupon, and on a certificate of such filing being issued to him, he shall become exempt from further registration under the laws of another State.

(5) That, as to other features of motor vehicle laws, uniformity can be obtained only through such bodies as the present Congress on Uniform Laws, which meets each year with the American Bar Association, and is made up of commissioners appointed by the governors of the different States, one of whom at this time fortunately is Charles Thaddeus Terry, the attorney for the National Association of Automobile Manufacturers.

(6) That State associations and clubs can, perhaps, solve the problem more simply by securing from State legislatures provisions which shall exempt non-resident motorists from the registration features of their laws.

How far it is safe to leave so important a matter to revenue-seeking States should first be determined. If thought unwise—granting always that the legal views here suggested are correct—the legislative board should divide its work into two branches: (1) The preparation of a federal bill to prevent duplicate registration and numbering, and present the same at the opening of the sixtieth congress in December; and (2) after proper investigation and discussion, the drafting of a sample or model motor vehicle bill, which, when agreed to, should be presented to the Congress on Uniform Laws next August, to the end that the same may be presented to the various State legislatures for adoption. The federal bill, if enacted into law, would end the confusion, annoyance and expense due to multiple registration; the other might, in the end, eliminate State lines as to speed, penalties and rules of the road.

Only by a program which is equally broad can the association perform its duty to its members and American motorists generally.

Increased Membership.—An active campaign for new members should be begun at once. The association is already large, but, when compared with the number of motorists in the country, is really small. This condition can be easily remedied, and must be if the national body is to continue really national. Further, the increase must be geographical as well as numerical. Particular attention should be given those States where the motor vehicle is as yet little used, and centers of activity formed which shall combat existing prejudices and, if possible, shape future laws.

This work will naturally fall on the executive committee and the secretary, and plans should be at once made which will be both comprehensive and practical. Consistent and persistent work should result in doubling within the year not only the total membership of individuals, but also of the affiliated State associations and clubs. Each city and village of 10,000 population in, at least, the Eastern, Northern, and Middle Western States, should have an automobile club, and such clubs should, as soon as possible, be federated into State associations. To these ends, there should at once be prepared circulars detailing the advantages derived from membership and outlining the steps necessary to club organization, with sample by-laws to help toward uniformity. The present individual membership of the association should be the nucleus of this work.

Finances.—The work just outlined will require funds considerably in excess of the membership revenues of the association. Fortunately, due to the careful management of the last Vanderbilt Cup Race by the retiring racing board, the association begins the fiscal year with a goodly surplus. A similar addition to the treasury is expected from the race in October. Increased membership, too, will correspondingly increase our revenues. But great care will be required to keep expenses down. Indeed, other means of raising revenue may perhaps be required, and sooner or later the association must adopt a financial policy which will put at its disposal from dues alone sufficient funds to do its work.

Roads and Parkways.—As already suggested, the function of the national body is here but advisory. The day has not yet come when federal aid can be expected, much less counted on. Present

(Continued on page 201.)

PREDETERMINATION OF MAXIMUM MOTOR POWER*

By R. ARNOUX, VICE-PRESIDENT TECHNICAL COMMITTEE, AUTOMOBILE CLUB OF FRANCE.

WE have just seen how in a motor of given dimensions, varying with the angular velocity, the power increases. It now remains for us to note how these elements increase with the geometric dimensions of the motor. For this we must still consider the equation (8), which may be stated as follows:

$$\frac{P}{\pi D^3 C} = p_m \cdot \frac{\omega}{2.60} \quad (12)$$

Since the study of a motor of given cylinder capacity shows that the product of the average pressure by the angular velocity (which product is equal according to this last equation to the volumetric power, that is the relation of the power to the volume of the cylinder) reaches a maximum and that at this maximum the function preserves a high constant value, it may be asked if, in view of this experimental constant, it would not be possible to establish a predetermined formula of the maximum power of explosion motors, in which only the cylinder and one of its geometric dimensions, such as the bore for example, would enter.

With this aim in view, we have compiled in Table No. 1 the data resulting from experiments made with 96 motors of varying dimensions and types of construction. This table gives the diameter of the bore, the total piston travel, the maximum power and the angular velocity of each motor, expressed in turns per minute at which this maximum power is developed. All of the motors from which the data were drawn for the table in question were of the four-cylinder vertical four-cycle type having but a single piston in each cylinder; their cylinder diameter, or bore, varying between a range having 65 mm. as its minimum and 190 mm. as its maximum; their cylinder volume varied between .9 and 16.25 liters, their maximum power between 10 and 148 horsepower, and their angular velocity between 950 and 1,650 turns per minute. Particularly where the factor of angular velocity is concerned, it will be noted that this element varies but little, as its value in the case of the least powerful motor, No. 1, was 1,450 r. p. m. and but 1,250 r. p. m. for the most powerful motor, No. 96. Regarding the mean linear speed of displacement of the piston, this was 3.62 meters per second in the case of the first motor developing 10 horsepower, and 7.70 meters per second or more than double, for motor No. 96, developing 148 horsepower.

Tabulated Results of Extensive Experiments.

An examination of this table in which the motors are grouped in the order of the diameter of their bores, demonstrates that, among motors having the same diameter bore, it is not those which have the longest stroke, and in consequence the greatest volume, which develop the greatest power, and as we are striving to derive a formula permitting of the predetermination of the maximum power that a motor of given cylinder dimensions can develop, we have chosen among the 96 motors of Table 1 those which developed the maximum power with regard to their cylindrical volume. By carrying the volumes on the abscissæ and the corresponding powers on the ordinates, we have obtained the alignment of the 12 points shown in Fig. 2. If the relation of the power to the volume of the cylinder, a relation to which we have applied the term "the highest volumetric power," were constant and, in consequence, independent of the dimensions of the motor, the 12 points shown on Fig. 2 would be ranged along a straight line rising directly from its point of origin. Now, if this relation be calculated by taking motors which are extreme instances, it will be found that the volumetric power reaches 12.55 horsepower per liter in the case of the weakest motor and drops to 8.31 horsepower per liter in the case of the

most powerful. After that it was quite clear that it was necessary to attempt to make these 12 points on a parabolic curve of the form of

$$P = kVn,$$

in which *k* is a parameter of similitude, *V* is the total volume of the cylinders and *n* an exponent less than unity. This parabolic, of which the axis coalesces with the line of the abscissæ, is the following:

$$P = 11.1. V, 9,$$

which gives the maximum power, in horsepower, obtainable from a motor of total cylindrical volume *V*, expressed in liters or cubic centimeters.

Volumetric Power Decreases as Dimensions Increase.

This is of interest in that it demonstrates definitely that the volumetric power of the internal combustion motor decreases constantly in proportion to the increase of its dimensions, and in consequence of its power. We have already demonstrated above that this volumetric power is equal to the product of the mean pressure by the angular velocity, a product which we have

TABLE NO. 1.—Data from experiments made on 96 four-cycle, four-cylinder motors, one piston per cylinder.

* Translated from "Bulletin Officiel de la Commission Technique." By Charles B. Hayward. Continued from pages 49-51, issue of January 10.

further shown is proportional to the density of the mixture at the end of the aspiration by the frequency $\frac{\omega}{260}$ of that aspiration. As the variation of that frequency is very small, as may be seen by reference to Table I, the conclusion is that the density of the explosive mixture corresponding to the maximum power developed by an internal combustion motor, decreases constantly in proportion to the growth of its dimensions and the power of the latter.

It is easy to see that this depends on the length of the gaseous column contained between the air inlet of the carbureter and the head of the piston, a distance that is necessarily augmented with the increase of the linear dimensions of the motor and in consequence, with its power. In fact, that which regulates the power of the internal combustion motor is not the loss in volume of the aspiration, nor the relation of the gaseous volume aspired to the duration of the aspiration, which increases without limit with the angular velocity of the motor, but the loss in weight, or loss of mass. It may easily be demonstrated thermodynamically that the latter passes a maximum in the same time that the function,

$$\frac{\sqrt{L \cdot r}}{r}$$

in which *logê* designates a Napierien logarithm and *r* the relation of the upward pressure to the downward pressure. The maximum of that function is obtained by reducing its derivative to zero,

$$\frac{1}{r^3} - \frac{2}{r^2} \log_e r = 0$$

which gives:

$$2 L \cdot r = 1,$$

from which:

$$L (r^2) = 1 = \log_e e.$$

$$r = \sqrt{e} = \sqrt{2,718} = 1,649$$

where the inverse is equal to 0.6065. This is then the depression produced by the displacement of the head of the piston, which is the direct function of the speed of that displacement, reaching (1-0.6065) or 0.4 of an atmosphere, of which the loss (relative to the mass) of the gas inspired reaches a maximum. The reason for this maximum is easily discernible owing to the fact that the fluid is highly compressible. The loss in volume evidently grows without limit with the speed of the motor, but the density of the gaseous mixture and in consequence, the work of the cylinder, tends, on the contrary, toward zero.

On the other hand, the loss in weight of the gaseous mixture, which is the direct function of the depression and inversely of the density of the flowing mixture, reaches a corresponding maximum, as we shall see, at the depression of 0.4 of an atmosphere. But the gaseous fluid, flowing under that difference of pressure, has to travel a distance increasing with the geometric dimensions of the motor, and its loss in weight, which regulates the power developed, varies, all other things being equal, as may be shown thermodynamically, inversely with the length of the inlet piping. Independently of the diameters given to the latter as well as to the valves, it is that length of the gaseous column contained between the air inlet of the carbureter and the head of the piston, which compels its reduction as much as possible as well as giving rise to the necessity for equalizing it between the different cylinders, where it is desired to produce the maximum amount of power from a cylinder of given dimensions. Builders of motors giving a high actual horsepower for aviation, as well as high power for their weight, have solved the problem by placing the carbureter in the immediate vicinity of the inlet valve of each cylinder.

The Bore With Relation to the Maximum Power Obtainable.

The predetermination of the maximum amount of power of an internal combustion motor, given one other element beside the cylindrical volume, the bore, for example, has occupied

engineers closely for the past three years. M. A. Varlet, engineer of the Delahaye works, first proposed, in 1903, a formula based on the square of the diameter of the bore, which has been revived very recently by the Technical Commission. The fact which led M. A. Varlet to propose such a formula, was the constance of the linear speed of the piston, a speed which, with the, at that time, almost universal employment of the automatic inlet valve, varied but little with the geometric dimensions of the motors and, in consequence, with their power. It may be readily demonstrated, in fact, that if this linear speed be designated by *v*, there will result, employing the preceding notations:

$$v = \frac{2 C \omega}{60}$$

from which:

$$\omega = \frac{60 v}{2 C}$$

and in carrying that value of ω to the equation (8)

$$P = \frac{\pi \cdot v \cdot p_m}{16} \cdot D^3$$

an expression, independent of the travel of the piston, which may be reduced to a parabolic function of the second degree,

$$P = K D^2$$

in which *K* is a constant, if it be admitted that the mean pressure *Pm* corresponding to the maximum power, is equally con-

TABLE NO. 2.—Maximum power output (in horsepower) of four-cylinder motors with regard to the diameter of their bore (in millimetres).

FIG. 2.

stant in all motors, or independent of their dimensions. It is further clear that the same result will be obtained by admitting the constance of the product of the mean pressure P_m , by the speed of displacement of the piston.

There is but a single method of verifying the accuracy of that formula, which is that of comparing the results it furnishes with those directly obtained by experience. This is what has been done in the compilation of the chart Fig. 3, on which the bore diameters, expressed in millimeters, are carried on the abscissæ, and the corresponding maximum powers expressed in horsepower (chevaux) of the 96 motors tabulated in the first table. These powers are indicated by the points, each of which is surrounded by a small circle. Despite the considerable differences in power represented by motors of the same diameter of bore, it will be seen, nevertheless, that the law of increase of these powers where the bore is concerned, indicates a net parabolic curve; but it is indicated clearly by the tracings of the parabola of the second degree:

$$P = 0.0028 D^3$$

so that if the parameter K be calculated in such a manner as to give the exact values, that is, equal to those of the mean corresponding to current bore diameters between extremes of 85 and 105 millimeters, they give powers slightly superior to those shown by actual experience in the case of small motors, and very much less in the case of motors of large bore. The degree of the parabola KD^3 is then itself very weak.

For this reason we have been engaged for the past several months in the attempt to establish another parabolic formula in departing from the following hypotheses. In lieu of assuming the geometric dimensions to be constant and independent of the product of the mean pressure by the linear speed of the piston, the product of that same pressure by the angular velocity may be considered as practically constant, which appears to be the result drawn from the results of experimental tests on a lot of thirty motors, the data of which we have in our possession at the moment. Under these conditions the formula (8) demonstrates that the power of the internal combustion motor is proportional to its cylindrical volume. On the other hand, experience shows that, all other things being equal, as the travel of the piston is increased or diminished, the angular velocity corresponding to the maximum power of the motor varies in an inverse sense, so that the product of the travel by that angular velocity reaches a maximum practically corresponding to the square of the bore, that is, a stroke equal to the diameter, which gives the formula of the cube of the diameter of the bore:

$$P = 0.000025 D^3$$

which was published by our colleague, M. Lucien Perisse, in his study on the Estimation of the Power of an Automobile Motor,

which appeared in August, 1906, in the *Bulletin de la Commission Technique*. At the moment, the results furnished by that formula agree quite correctly, as shown by page 40 of the work of our colleague, with the results of the experimental tests which we had at that time. Since the data of the experimental tests collected by us in working on another lot of 60 motors, and carried on the same chart, Fig. 3, together with the preceding lot, at the same time that cubic parabola,

$$P = 0.000025 D^3$$

were traced, making it clear that in furnishing figures more in accordance with the experimental results of the experiments, than those of the parabola of the square of the diameter of the bore, the degree of the cubic parabola is very high, since the inverse of the parabola of the square gives very weak values for the powers of the motors of small bores, and very high for those of large bores, if its parameter K be calculated for that which gives exact values for medium bores.

The degree of the representative parabolic function KD^n is contained between two and three. M. Farnoux, technical editor of *L'Auto*, after having adopted the exponent 2.15, manifestly too feeble, has proposed the use of the exponent 2.4, which, according to our calculations, gives a parabola on which the variation of the curve follows more faithfully that of the curve relying on the most elevated points of the basis furnished by the experimental tests charted in Table 1. The parabolic formula which we have adopted, and which is a formula of the maximum, that is, making clear the maximum power obtainable from a standard motor of given bore, is the following:

$$P = 0.000525 D^4$$

This gives in horsepower (chevaux) the maximum power obtainable from four-cylinder, four-piston motors, of which the bore is expressed in millimeters. The calculation of the power with that formula necessitates the employment of a table of logarithms, for which purpose we have calculated and compiled Table 2, which gives these results instantly from one horsepower up, the maximum power obtainable from internal combustion motor built according to standard practice, given the diameter of the bore.

Electric cabs in Berlin provided with Hagen accumulators run on an average 37 miles per day and have to be charged twice. *L'Industrie Electrique* gives the cost of working as follows: Energy, 4.25; maintenance of accumulators, 3; sundry repairs, 1.25; maintenance of tires, 4.38; making a total of 12.88 francs per diem. Average receipts per fare are 2.15 francs.

FIG. 3.

LETTERS INTERESTING AND INSTRUCTIVE

A Problem in Cylinder Lubrication.

Editor THE AUTOMOBILE:

[538.]—I am a constant reader of your valuable paper and have derived many benefits from your answers to your subscribers, and thought no doubt you could help me. I have a four-cylinder Ford runabout. The engine is splash lubricated from a force feed oiler. The oiler has only two sight feeds, one leading to the universal joint and the other to the crankcase. The latter feed pipe enters the crankcase in the middle, and should, I suppose, feed the same amount of oil to both pairs of cylinders, as the crankcase is divided into two compartments. This, however, is not the case. The first cylinder gets an excess of oil, the second a little less, and so on, and the last cylinder gets hardly no oil at all. Could you offer any suggestion which would remedy this fault?

Raleigh, N. C.

JAS. J. THOMAS, Jr.

From our knowledge of the car to which you refer, we can scarcely bring ourselves to believe that the unequal lubrication you mention can exist with everything in proper adjustment, especially in view of the fact that we have never heard of a similar difficulty with any other car of the same make, several thousands of which are in use. What evidence do you find that makes you sure the trouble exists as you state it? Is there any serious overheating, or scoring of cylinders, or seizing of pistons? And, also, are you sure that you are using oil of a proper quality? The fact that there is only a single lead to supply the lubricant for the four cylinders has little bearing on the case, unless the lead is obstructed or feeding too slowly, since if there is enough oil in the crankcase its effective distribution to the different cylinders should be insured by the splash action alone, especially on level roads. On hills, with only the single crankcase partition, the distribution might be slightly less even than with the three-partition construction often utilized, but this effect is practically very well equalized in that you do not run continuously uphill or down, but alternate the two. Do you find the fault especially intensified in climbing long grades, and are you certain that you maintain a high enough level of oil in the crankcase?

Another Ambitious Young American.

Editor THE AUTOMOBILE:

[539.]—Kindly print in your valuable paper the answers to the following questions. I am a boy 16 years of age, and am trying to make an automobile. Can I use a marine motor in an automobile? The name of the motor is the "Little Skipper." If a boy had an auto that made at highest speed eight miles an hour, would he have to get a license? How can you get one, and does it cost anything? Could he run it himself? Will you kindly print a list of books on how to make an auto, with their prices?

New York.

VICTOR J. CONDE.

As your ambition does not soar above eight miles an hour, the marine motor can be used in an automobile—if it has power enough to move the frame and running gear on which you mount it. The only difference between the usual marine motor and the automobile motor is greater weight and slower speed, particularly as most small marine motors are of the two-cycle type. This does not prevent its use on an automobile, however. Whether your car makes eight or eighty miles an hour, the law says that it must be registered, cost \$2. Send to the Secretary of State, Albany, for application blanks. But if you are on the right side of the policemen in your neighborhood, better keep the \$2 and say nothing. It is doubtful if your car will ever fracture the speed limit so badly that you will have to appear in court, and the average guardian of the law will be more interested in your success in building a machine than in inquiring if you have a license. No license to run it will be required. You may run it yourself, just as long as it will go. There are no books that treat specifically on how to build an automobile, but there are many which show how automobiles are built, such as Homan's at \$2, which is probably the best for your purpose.

Specific Gravity of Anti-freezing Solutions.

Editor THE AUTOMOBILE:

[540.]—I am interested in the subject of anti-freezing solutions for winter use, and although I have closely followed everything that has appeared on the subject both in "The Automobile" and elsewhere, I have been unable to obtain the information I am seeking. I am familiar with the exact percentages required to prevent freezing at certain temperatures, but I wish to know what the specific gravity of these solutions is in order to be able to keep track of the condition of the mixture from time to time, as my car steams slightly when run steadily even in cold weather. For instance, a 25 per cent. solution of calcium chloride will withstand temperatures ranging from 10° F. to zero, and will freeze into a mushy mass, doing no harm, but unless such a solution is maintained constantly at this point it is apt to do damage by crystallizing on the interior of the jackets, piping and radiator. As there is no way of calculating the amount of water lost by steaming, there is the danger of creating a hard deposit by adding too little water, and of overweakening the solution by adding too much, so that in the event of freezing, the very damage that is sought to be prevented is apt to occur. If the specific gravity of solutions of various strengths were known, it would be easy to keep track of their condition simply by dropping a hydrometer into them from time to time and adding sufficient water to restore it to the known standard. What I would like to know is, what is the specific gravity of solutions of calcium chloride in the proportions of three, four and five pounds to the gallon, also a saturated solution? Can any of your readers help me out on this, particularly with regard to the saturated solution?

H. S. CHAPIN.

New York City.

Although data as to the temperatures at which solutions of water and calcium chloride of varying strengths will freeze appears to be plentiful, there does not seem to be any as to the specific gravity of such solutions. However, with the aid of a hydrometer there should be no difficulty in obtaining it with very little trouble. Take a glass graduate holding a pint or quart and fill it with water; if the former add a quarter pound, and in the case of the latter half a pound of calcium chloride, and the result will be a 25 per cent. solution. By ascertaining the number of quarts of water required to fill the circulating system of your car, it will be very easy to figure how many pounds of calcium chloride should be added to make a 25 per cent. solution. The specific gravity of a saturated solution can be ascertained in the same manner. A simple method of keeping track of the state of the solution without the use of a hydrometer would be to mark a line on the radiator reached by the solution when first put in. Whenever steaming caused the liquid to fall below it, sufficient water to restore it to the level indicated by the mark would be certain to maintain the solution at the required density. If any readers of THE AUTOMOBILE have had experience along the lines indicated, we should be pleased to hear from them.

Putting Away Storage Battery for the Winter.

Editor THE AUTOMOBILE:

[541.]—Will you kindly tell me if there is a dry storage battery made that can be charged with an Apple dynamo? I have understood that there is such a battery made, also if such a battery (if there is one on the market) would stand all winter and not be used could be charged in the spring without refilling. I have a storage battery in a four-cylinder car, and during the winter months the car is idle, as we do not have good roads to run on, and would like to know what is the best thing to do with a battery where it is idle for this length of time.

D. T. DUKE.

Wellsville, N. Y.

There is no such thing as a "dry" battery of any kind, using the word in its literal sense. The so-called dry cell is only such in the sense that the active solution is held in suspension by means of some absorbent material, such as sawdust. The object of so doing is merely to eliminate the disadvantages attendant upon the use of a liquid, the efficiency of the cell being slightly impaired by reason of the fact that the solution cannot circulate, thus coming into constant contact with every part of the elements, as is the case in the wet cell. The same is true in the

case of the accumulator, except that what is commonly known as "water glass" (silicate of soda) is employed to prevent splashing. Sufficient of this is added to the electrolyte or acid solution of the cells to bring it to the consistency of a heavy jelly, somewhat like glucose. It is variously termed by makers putting out this type of cells as "solid" or "non-fluid" electrolyte, and its sole advantage consists of the fact that the solution cannot spill. On the other hand, the specific gravity of the solution cannot be kept track of, the efficiency is reduced for the reason already given in the case of the dry cell, and a longer time is required to recharge the cells when exhausted. On the whole, it is paying a rather high price for the single advantage mentioned.

Such a storage battery can be readily charged with an Apple dynamo or any other source of direct current of the proper voltage. As already stated, the only difference between it and the standard type lies in the use of a non-fluid electrolyte. No storage battery made can be put away for an indefinite length of time and impressed into service again whenever wanted without taking certain precautions. If they are omitted the cells are bound to be injured. They should be charged to their full capacity and then fully discharged at their normal rate until the voltage drops to 1.7. The electrolyte should then be dumped out and the elements washed in distilled or fresh, clean rain water and put away in a cool, dry place until wanted again. To put into service in the spring it is only necessary to fill with fresh electrolyte made from chemically pure sulphuric acid and distilled or rain water, testing it with a hydrometer to get the proper specific gravity. Fill the cells until the solution stands at least one-half an inch above the top of the plates.

What Causes Irregular Running Here?

Editor THE AUTOMOBILE:

[542.]—I read with much interest the article in your issue of January 3, written "By the Man at the Wheel." I have a French car, 24-horse rating, and have lately experienced a great deal of trouble with it. In starting the car when cold I find that only two or three of the four cylinders fire, and this difficulty is accompanied by a popping sound in the carbureter, indicating that the mixture is too poor. After the car is run for a few minutes and warmed up the cylinders seem to fire regularly, but the car is very prone to "lay down" whenever the throttle is open wide.

I have carefully examined the inlet and exhaust valves on starting the car, and find they all work freely, as do the hammers for the make and break. I have taken off the carbureter repeatedly and find I have a strong flow of gasoline from the end of the pipe leading into the carbureter, and the openings in the carbureter are clear and free from any dirt or foreign substance. I recently removed the carbureter from this car, and installed a carbureter from another car of the same make and power, which car runs beautifully. For twenty minutes after installing this carbureter my car ran perfectly, and then relapsed into the same way of running as it had with the other carbureter. The gasoline feed is by gravity, and I have carefully examined the small hole in the vent of the cap, which is not clogged up.

On opening the throttle suddenly the car will sometimes pop back, which would show there was not enough gasoline in the mixture, and at other times the car will "buck," which would indicate that the mixture was too rich. I have raised and lowered the float in every conceivable position, and have also adjusted the automatic air valve in a dozen or more different ways without seeming able to remedy the trouble.

As the matter now stands, my car does not run nearly as well as it did, and there is not much pleasure in driving a car which you know is not behaving properly. I would be very glad to have you suggest a remedy in the columns of your magazine.

Passaic, N. J.

"PERPLEXED."

In view of your experience and that of the alleged "experts" who have attempted to arrive at a solution of the cause of the trouble outlined in your letter, you will be able to appreciate that it is doubly difficult to attempt to diagnose such a case at long range. We think, however, that you have made a mistake common to most autoists under the circumstances, and that is in jumping at conclusions. You have adopted a hypothesis and assumed it to be true, and have continued to work along the same line so long that you have come to regard it as true

and as if nothing else could be at the bottom of the trouble. For instance, you say, "the car will sometimes pop back, which would show there was not enough gasoline in the mixture, and at other times will 'buck,' which would indicate that the mixture was too rich." While we cannot exactly grasp the significance of "buck" in this connection, we presume you mean that the motor loses power, or fails to carry the load when the throttle is opened. But there are few, if any, conditions of running that are infallibly indicative of a certain cause, such as your conclusion that the popping is due to a weak mixture, or that the "bucking" is the result of a reverse condition. The majority of autoists fail to realize within what extremely wide limits of mixture the engine will work satisfactorily once it becomes warm enough to insure ignition, and are all too prone to ascribe uncertain working to the mixture. If the motor has been running a sufficient length of time to get warm, it will usually ignite mixtures far too weak or too rich to start on, though the power will be decreased in either case and the fuel consumption be greater in the latter.

Judging from the data you have given, the trouble appears to be more apt to lie in a poorly fitting valve or valves, or a leak in the inlet manifold. A valve may leak in such a manner that at times it permits considerable of the compression to escape and at other times does not. When it does it will drive all mixture out of the manifold and carbureter issuing at the air inlet of the latter with a popping sound. For instance, cylinder number one has just fired, but on its compression stroke it has emptied the piping system so that cylinder number three, which is next in order, receives no charge and misses. It will then depend on whether the system recovers sufficiently in the interval to supply cylinder number two with enough of a charge to fire at full power. On the next round cylinder number three may inspire sufficient charge to fire, and then the compression of the explosion escaping through its leaky inlet valve will rob cylinder number two of its charge, thus causing the miss to apparently jump all over the engine in a most puzzling manner. Without further knowledge of the conditions, we should suggest an inspection of the valves to see if they require grinding in. Placing the ear close to the manifold where it is fastened to the cylinders will reveal whether there is any escape at those points.

More Light on Average Current Consumption.

Editor THE AUTOMOBILE:

[543.]—I fear that there is one point in particular little understood by the automobilist, and that is, that the battery consumption is the same at all speeds of the car. The general impression is that, as the spark is advanced or as the speed of the car increases, so does battery consumption. In a four-cylinder car, for instance, the time of contact for each cylinder is approximately 1-12 of a revolution. There being four contacts, the actual time of contact is one-third of the time run; so that if you drive your car for one hour it is equivalent to turning your switch on and letting it run for 20 minutes. For a two and one-cylinder car it would be practically one-half or one-fourth of the above, although the time of contact for each point is greater on a one and two-cylinder car than on a four. Is there any kind of solder and flux that can be used on aluminum?

CLARENCE T. JONES.

Columbia, S. C.

We very much fear that instead of the majority of autoists being misinformed on the point in question, your own knowledge is somewhat at fault. However, this will depend entirely upon the meaning you intend to convey by the expression "battery consumption." If you mean that the amount of current required to cause the spark to take place in the cylinder regardless of the time of occurrence or rapidity with which it occurs, due to the increased speed of the motor, remains the same, this is quite correct. In other words, neither advancing nor retarding the time of occurrence nor increasing the speed of the motor causes the latter to draw more current *per spark* from the battery. But it appears evident from the second paragraph of your letter that you wish to convey the impression that regardless of the speed of the motor the total amount of current drawn from

the battery is the same. As you say, the time of contact is approximately one-third of the time run, but in the case of a motor running at 1,500 r. p. m. contact is made twice as many times in the same period as if the motor were only turning over at 750 r. p. m. Your error lies in assuming that the period of contact is always equivalent to a constant contact, or closed circuit on the battery, for that length of time. If this were the case the dry cell would be worthless for automobile ignition. Turning on the switch and letting the current pass through the coil continuously for twenty minutes would be equivalent to considerably more than an hour's running of the motor. The impulses, or current discharges from the battery, are intermittent, and even though the motor be run at a very high speed they are not equivalent to the current consumed by the same coil on closed circuit. But the higher the speed the more frequent they are and the closer they approach to this value, hence the current consumption increases with the speed. The same amount of current is required *per spark*, but there are twice as many sparks in the instance cited. Just what proportion the increase in current consumption bears to the speed is, however, difficult to state. Novel's solders for aluminum are 100 parts tin to 5 parts lead or zinc; or 1,000 parts tin to 10 or 15 parts copper or nickel; no special flux is mentioned. Another formula consists of one part aluminum, one part 10 per cent. phosphor tin, 8 parts zinc, 32 parts tin, all by weight. With this Canada balsam is used as a flux. Considerable skill is required.

The Origin of the Term Limousine.

Editor THE AUTOMOBILE:

[544.]—Can you tell us anything about the origin of the term "limousine," used to designate a type of covered-in automobile? We should like to know how the word came to be applied, when it was first used, and whence it is derived. Can you supply us with this information? Thanking you in anticipation of a reply.

New York.

FUNK & WAGNALLS COMPANY.

The word "limousine" is of French origin and was originally applied to an open type of carriage body. A few years ago its significance was completely transformed, and it is now applied to any type of closed carriage which cannot be classed among such standard types as coupé, landaulet, omnibus, etc., whatever may be its form, dimensions, or number of places. The term "limousine" was first given to a new type of carriage designed by a Paris coachbuilder, a native of Limousin, one of the old French provinces.

A Time-honored Question Is Again Asked.

Editor THE AUTOMOBILE:

[545.]—Will you kindly tell me if there is any book published describing and telling how to care for a steam automobile? Also which is the freest from trouble and cheapest to operate, a gasoline or a steam automobile? I should judge the steamer would be best because it would be free from ignition troubles, but would like your opinion.

Freeport, N. Y.

LAWRENCE H. WRIGHT.

We do not know of any work that treats exclusively of the steam automobile and its management, but Holman's book includes chapters on the various types of steam cars extant as well as those of former days, and goes into detail regarding them as well as the care they require. It is generally conceded that in the advanced form in which it is now employed, steam is more free from minor troubles than the gasoline motor. As a well-known engineer has expressed the matter, "it takes two hours to find out what the trouble is with a gasoline machine and five minutes to remedy it, whereas only a glance is necessary to see what is wrong with the steam plant, but two hours are required to put it right." The question depends wholly on your own views in the matter; if you are familiar with steam practice you will probably like it better than gasoline, and *vice versa*. But reliability has been brought to such a high point that you run very little chance of disappointment in buying a standard car of either type. As to relative economy, this is a hard

question to answer; the steamer burns considerably more fuel per mile than the gasoline car of the same weight, the former only doing nine to twelve miles per gallon, while the latter covers fifteen to twenty-two or more. More lubricating oil is required for the gasoline machine, though in other respects there is probably no difference in the cost of maintenance.

Extent of the Gasoline Engine Demand.

Editor THE AUTOMOBILE:

[546.]—Will you kindly inform me where I can obtain information regarding the extent of the demand for gasoline engines? How many are made annually in the United States? To what extent are they used for farm work, for trucks, etc., for propelling boats other than launches, and on railways.

Toronto, Ont.

GEORGE DICKSON.

We doubt if any definite statistics on this subject are available. The number of gasoline engines of small powers annually produced in this country for farm and similar work is very large, mounting up into the thousands, and though to a much lesser extent, the same is probably true of small marine motors now being made for commercial purposes, such as fishing dories and the like. Their use on larger vessels or railways is at the present writing more in the experimental stage than otherwise. The International Harvester Company, Chicago, Ill., might be able to give you some idea of the number manufactured for farm work.

WINCHESTER, VA., FIRE DEPARTMENT WANTS.

Editor THE AUTOMOBILE:

[547.]—The general requirements upon which bids are invited by the Winchester fire department from manufacturers of an auto hose truck are that it shall be capable of carrying a load of about 2,500 pounds above its body weight. This load includes the fire hose, men, ladders, chemical tank, axes, picks and buckets. A gasoline engine is preferred, either water or air-cooled, to have gear of 16 to 20 miles per hour on levels, to be operated on vitrified brick and macadam streets, few grades and not over 10 per cent.; to carry 800 to 1,000 feet of regulation fire hose, one chemical tank with 200 feet of chemical hose, with basket to hold same, two hand chemical tanks, conveniently located, one extension ladder and one solid ladder, two picks (or pikes), two axes, six rubber buckets and a running board at the back for men.

Small deviation from the above is permissible, and all bids and correspondence should be addressed to the undersigned as soon as possible. Bids should be accompanied with complete specifications and blue-print or photograph if possible.

Winchester, Va.

J. FRANK EDDY & BROTHER.

A SUCCESSFUL HOME-MADE INSTALLATION.

Editor THE AUTOMOBILE:

[548.]—Noting the experience of your correspondent, letter No. 482, issue of November 29, in which he states that he always had trouble with the ignition system of his car and wishes to install a high-tension magneto, I will tell you of the success that I have had with the Apple dynamo, in order that others may benefit thereby. I fitted one of these little generators to an Elmore single-cylinder car nine months ago. There was a Pittsfield coil on the car already, and I did not disturb or alter it in any way. Nor did I use a storage battery. The dynamo is fitted with a three-inch friction pulley bearing directly against the flywheel of the engine, and when running up to speed delivers its output at 12 volts. I used two 6 c.p. lamps for the side lights and a tall light of the same size. The dynamo runs these three lights and sparks the engine at the same time. I use no storage cells nor dry battery, and have never had any trouble starting with the dynamo, nor has the outfit given me a moment's trouble since installing it. I trust this may help 482 as well as others in the same predicament.

Corisicana, Tex.

CLARENCE THOMAS (Auto Doctor).

FROM AN OLDSMOBILER TO OLDSMOBILERS.

Editor THE AUTOMOBILE:

[549.]—With regard to letter No. 517, re heating of the 20-horsepower two-cylinder Olds touring car, I have found from experience that these cars heat more in cold weather than in hot, because there is not sufficient steam vent given to the radiator. If the hood is taken off the car, and then a quarter inch hole drilled in the back of the radiator close to the top, the water will circulate and steam pockets will not form in the cylinders.

London, Ont.

W. F. H.

MODEL G, SERIES 2, ROYAL TOURIST, WITH KING OF BELGIANS BODY.

ADHERING steadfastly to the maxim about "doing one thing well," the builders of the Royal Tourist car have persistently stuck to the plan of specializing one type of chassis and one only, during all the time that this well-known car has been on the market. This is an age of specialization and the success that has followed the adoption of the plan of doing one thing well in the numerous lines in which specialists have scored, finds no exception in the case of the automobile. More than that, the builders of the Royal Tourist have appreciated the value of retaining the original outlines of a car which give it a distinctive character of its own and serve as a means of identification. For this reason not alone the outward appearance of the new model for the coming season but, at first glance, the motor, looks to be exactly the same as has always constituted a distinguishing feature of this car. This may seem to savor of extreme conservatism, but that this is not the case may best be judged from the close attention given to the matter of keeping abreast of modern design, as well as in adding exclusive improvements in the nature of detailed refinement to the motor and other parts of the chassis.

For instance, to summarize the improvements that distinguish the 1907 model from its predecessors, the motor, which is the four-cylinder vertical type, with cylinders cast in pairs measuring five by five and a half inches and developing 40 horsepower, originally designed by the Royal engineers, has

been provided with stuffing compression boxes on the valve lifters to prevent leakage of oil or grease out of the cam pockets. All joints in the crankcase are scraped to a perfectly flat and true surface, so that no oil can be forced out of the crankcase; the end bearings of the crankshaft are provided with return oil ducts, so that oil from these bearings does not escape but is returned to the crankcase and is utilized for the splash lubrication of the pistons and big ends of the connecting rods. The camshaft gears are entirely inclosed, as is also the gear driving the magneto. Simms-Bosch high-tension magneto is employed, provision being made on the motor in the shape of a high-tension switch, so that either accumulator and coil ignition or magneto ignition can be used with the same set of plugs. An arrangement has been provided on the fan pulley in order to permit of tightening the fan belt readily. The belt itself is flat and is made of non-stretching material. The wiring from the magneto has been

entirely inclosed and is so arranged that leakage of the current is practically impossible. Similar protection is given the wiring leading from the coil, avoiding the possibility of dirt accumulating under the latter. The motor and connecting rod bearings are of nickel-babbitt. For ignition a set of accumulators of greater capacity than were employed last year have been provided and the spark control has been arranged to work easier than was previously the case. An aluminum battery box

HOW THE CHASSIS LOOKS WHEN RELIEVED OF THE BODY.

TRANSMISSION EXPOSED, SHOWING DETAILS OF SLIDING GEAR.

of substantial construction has been provided to house this essential.

The crankcase vents, or "breathers," have been carried further up in order to prevent oil being sprayed about on the inside of the hood.

Similar provisions to guard against the loss of oil from any of the moving parts is noticeable in the oil retainers on the change-speed gear box. This is an excellent feature, as it is noticeable that many cars drop far more oil on the road than they employ in the actual work of lubrication—in fact, the loss is so excessive from this cause alone as to be hardly credible.

Carburetion and Lubrication.—As the result of experiments carried out during the past year a new type of carbureter has been adopted for which greatly reduced fuel consumption is claimed under ordinary conditions of running, without at the same time raising this unduly when the maximum speed of which the car is capable, is desired to be maintained. It is of the customary float-feed, automatic, compensating type, with a spring-controlled piston type of auxiliary air intake. It is placed at the level of the camshaft, on the same side as the magneto, the use of a common inlet valve pocket on each pair of cylinders simplifying the manifold.

Lubrication is provided for by means of a McCord type of mechanical forced feed oiler, with independent leads to the principal bearings, the overflow dropping into the crankcase and aiding in maintaining the level in the latter for the splash lubrication of the pistons and connecting rod big ends, as already mentioned. The oiler itself is mounted directly on the dash, and with the addition of the coil box completes the fittings of the latter.

DASH, SHOWING THE FEATURES OF OPERATION.

which presents an unusually neat and unencumbered appearance. They are supported on brackets formed on the dash itself. The arrangement of the oiler on the dash is such that none of the oil pipes are exposed to view, which prevents any leakage of oil onto the footboards or floor of the car. Both the footboards and the floor of the car are made in such a manner that they will not lose their shape. They are covered with rubber of a better grade than is generally employed for the purpose, and provision is made for its easy renewal in case of wear. The muffler is of an improved type, placed transversely across the rear of the car, and is easily dismantled and taken apart for cleaning.

Transmission and Drive.—An improved form of clutch pedal, the metal surface of which is covered by a soft rubber pad, has been adopted. This reduces the danger of the foot slipping off the pedal, the rubber being easily replaced when worn so as to be no longer of service. The form of pedal and lever employed also avoid the necessity of cutting a large hole through the footboard, and give it a neater appearance. The clutch is a leather-faced aluminum cone of the standard type, that has always been a feature of Royal Tourist construction. Between it and the gear box a universal joint is placed, while there are two on the propeller shaft, all of them being made of forgings of a special grade of steel, which gives them about double the strength, without an increase in weight over those formerly employed. The joint at the rear of the gear box is readily accessible,

REAR AXLE, SHOWING BRAKE MECHANISM.

and is made in such a manner that it is constantly lubricated at every point.

The change-speed gear-box is of the straight or progressive sliding type, giving three speeds forward. A novel and cleverly worked out arrangement is provided for shifting the gears, preventing to a very great extent the clashing or rubbing of the pinions while changing. This gear-shifting device is mounted on top of the gear box itself, and is connected to the gear-shifting lever by means of a train of gears, thus making the movement positive. All the pinions, as well as the shafts, are of chrome nickel steel, and the same material is employed in propeller and rear live axle shafts.

Running Gear and Suspension.—The frame has been made of a wider and deeper channel section, and has been lengthened by six inches over that employed last year, beside which the strength of the frame has been increased by about 50 per cent., owing to the use of a much higher grade of steel. The front axle is tubular, of dropped shape, and has also been improved in this respect. Steering arms and steering knuckles on the front axle have been increased in weight, a higher grade of nickel steel being used in their construction as well. The axle bed is made of nickel steel tubing, increasing the strength in about the same ratio as the steering arms, which are approximately twice as strong as those previously used. Both the front hubs and the front wheel bearings have been designed to carry a heavier load, the former having been increased in diameter. The steering gear has been improved in detail, with a view to overcoming wear and its resulting lost motion in as far as possible.

UNIVERSAL JOINT, BRAKE, AND RATCHET SPRAG.

The tubing used in the rear axle is of nickel steel, while the rear axle differential housing is made of a drop forging of special high grade steel. The large casing to which the torsion rod is attached has been heavily reinforced, in order to guard against any possibility of deformation. The brakes consist of one of the external contracting type placed on the rear of the transmission. It is operated by the pedal, and is for running service. The drum is of large diameter, and has a wide face, the brake shoes being readily adjustable, as well as detachable for replacement when necessary. In addition, this brake carries a ratchet sprag drum and pawl designed to be brought into action from the driver's seat. The strut rods to the frame from the rear axle have been made heavier in every way, and the same is true of the torsion rod running from the rear axle to the torsion buffer. This is made of a special grade of steel, and is twice as strong as the standard formerly adopted for this element.

HOW A ROYAL TOURIST LOOKS FROM THE FRONT.

This rod is drawn into the rear axle casing through a taper hole, making it impossible for the strain to gradually cause the rod to work loose. The rear brakes are of the internal expanding type, working on drums bolted to the driving wheels, and have been designed with such liberal proportions as to enable the rear wheels to be locked with the ordinary pressure on the hand lever, which has been improved by making it of the pull-up type, instead of requiring to be pushed forward to apply it. This is an apparently minor and trivial improvement in itself, but it demonstrates to what an extent attention has been devoted to improving the car in every detail. Some designers object to this method of application, on the ground that it spoils the appearance of the car by keeping this lever always in a forward position instead of vertically when at rest, as is the case in many instances. The rear brake shoes are also readily removable, to permit of replacing the liners in case of excessive wear.

For suspension, semi-elliptic springs of ample proportions are used on both front and rear, the spring clips employed on both axles being of an improved type, designed especially to hold the spring firmly on its seat, with a view to avoiding the possibility of the spring being loosened through constant bending, resulting sooner or later in its breaking. The running boards are brass bound all around, making them very neat in appearance. A full twelve inches has been added to the length of the tonneau, making it that much longer than any body previously fitted to these cars. This permits of the use of two extra folding seats, which provide ample accommodation for the average sized person, but which fold into very small compass when not in use, the extra length giving plenty of foot room to all the occupants of the tonneau. A coat rail is provided on the rear of the front seat, and suitable handles have been placed on the front seat and side of the body in order to make it unnecessary to put any weight on the side door when entering or leaving the car. The hinges of the doors have also been made heavier and of better material. The wheelbase has also been increased by four inches, making the car that much longer than its predecessor. In order to thoroughly protect every part of the mechanism from flying mud and water, pans extending rearward from the front end of the motor to the rear of the transmission case have been provided. They are bound with leather to prevent rattling, and are made fast to the frame with a number of wing nuts, so as to be readily removable for cleaning. They are so arranged that adjustments can be made on any part of the car without the necessity of disturbing the pans. No pains have been spared to make the upholstery and finish representative in every respect of the highest stage of the carriage maker's art. The mudguards have been improved by the addition of a deflecting strip running around the outside, throwing mud and water downward and stiffening the guard itself. The makers of the Royal Tourist operate their own body factory, which is one of the most complete in the country. Any body equipment that the purchaser desires can be furnished on the chassis described above, known as Model G, Series 2. In addition to the semi-oval outline of radiator that has always been a distinguishing mark of this car, a further means of identification has been added in the elongation of the filler vent.

A curious motor wheel is reported as giving satisfaction in England. The tire is compacted of a peculiarly tanned and waterproofed pigskin, dovetailed into a rim. It is therefore a solid tire; the leather wears on its edges, and is said to be almost like horn in hardness. Road shocks are absorbed by the hub, which appears to be a box full of small steel balls surrounding the axle. These slip so readily under sudden impact that the bearing is almost liquid in its mobility, and, unlike a spring device, it gives no reaction. Just how the wheel maintains a center about the axle with the balls free enough to allow of eccentricity does not appear. Apparently the play is limited by tubes through which the driving bolts pass freely, but limit the maximum up-and-down movement. Presumably when running the whole matter is self-adjusting.

INCREASING THE DOSE IS APT TO BE DANGEROUS

PROCEEDING on the principle that what is beneficial in small doses is correspondingly more so as the quantity is increased, many autoists are prone to resort to the use of additional cells of battery when, after considerable tinkering, they have been unable to get the coils in proper working condition. Just as powerful poisons may be taken in minute doses with good results and an excessive quantity seldom fails to prove fatal, so an excess of current above the limit for which the particular make of coil has been designed, is more apt to bring about its ruin than to restore the ignition system as a whole to that efficient state of working which is the object of the investigator in applying the remedy. Among the not very lengthy list of "don'ts" which the manufacturer of coils has compiled for the benefits of the users of his apparatus, this particular "don't" is written large. Yet, one after another, autoists will continue to travel the same road toward that expensive goal of experience, and in the majority of instances without realizing what they have done to end the working days of their coils until the secondary windings of the latter have been rehabilitated.

Despite the fact that the "innards" of a coil are regarded very much in the light of a mystery by the average man for the simple reason that they are never exposed to the public gaze, the why and wherefore of this particular reason for destroying the coil's usefulness is not difficult to understand. Technically speaking, the induction coil such as is used on nine cars out of ten is a step-up transformer—in other words, if a current of low tension such as is produced by a dry battery or a set of accumulators, or a small direct-current dynamo, is passed through its coarse or primary winding, a current of high tension or voltage will be produced in the fine or secondary winding. And by fine in this case is meant exceedingly fine, for the secondary windings of high grade coils are composed of 36 gauge cotton or silk-covered copper wire, and this, even with its silk insulation, is of scarcely greater cross section than a horse hair and is twice as delicate. It will be evident that the current-carrying capacity of such a wire is almost infinitesimal, and that an excessive increase over its rating, as calculated by the maker of the coil, is bound to either burn the wire or break down the resistance between the layers.

What the Addition of an Extra Cell Means.

"But," says the average automobilist, "how can the addition of one cell be considered excessive?" In the case of a dry cell this means but 1.1-2 volts, and of an accumulator but two volts. Such a query is naturally indicative of a lack of knowledge of the fundamental principle upon which the induction coil or transformer is based. This is the fact that the potential or voltage of the induced current is dependent, not alone on the proportion that the number of turns in the secondary winding bears to that in the coarse or primary winding, but also on the voltage of the current supplied to the latter. For instance, on the average coil for automobile use, the coarse or primary winding which is placed next to the iron core consists of two or three layers of No. 14 or 16 B. & S. gauge insulated copper wire. Assuming that in those layers there are fifty turns of wire round the core, and that in the fine or secondary winding there are 10,000 turns, then a current sent through this primary winding at a potential of six volts—that generally adopted for ignition purposes—would result in the stepping up of this pressure to one of 12,000 volts. These figures are naturally not those actually adopted by coil makers, but are merely assumed for the purposes of illustration. In the case supposed above, where the autoist who has decided that more battery power is the only remedy that will produce satisfactory ignition, adds another cell of storage battery to his ignition set, this merely raises its voltage to 8, instead of 6, but the extra 2 volts, when they have passed through the multi-

plying process of the turns of the secondary winding, mean an increase of approximately 4,000 volts, taking the ratio between the two windings as 1 to 200.

Why Extra Cells Endanger the Coil's Efficiency.

From this it will be at once apparent that the simple addition of an extra cell involves far more than an increase of two volts at the primary. It must further be borne in mind that insulation is the prime requisite of the secondary winding of the induction coil, and that when this is calculated to stand the potential resulting from passing six volts through the primary any increase in the latter is bound to overstep the limit placed by the maker on the capacity of the insulation of the fine windings to withstand the tendency to jump between windings or between adjacent layers. Just as a chain is only as strong as its weakest link, so the coil is no stronger than that part of it which presents the least resistance to the current, and in such a number of turns of fine wire there are bound to be numerous weak points, despite the greatest care exercised in the winding and insulation.

The danger is not merely in the number of cells employed, but in the voltage. For instance, four dry cells when new give approximately 6 volts, but, when nearing the end of their life, drop off somewhat, and it is then safe to add another, and the same is true of accumulators, except that when an accumulator has already dropped below a safe voltage it is not a good plan to couple two sets in an attempt to raise the combined voltage to that required. If the voltage, tested when running, does not exceed 1.7, further use of the cells in any way will damage them. They should be recharged without delay, and it is only by recharging at frequent intervals that proper service can be obtained from an accumulator. It is not to be denied, however, that adding an extra cell, and thus raising the voltage to 8 or more, will sometimes prove effective by improving the ignition to an extent that permits of running the car where this was not possible with the original number. But it only goes to show that there is a defect in some part of the system, which, if corrected, would do away with the necessity of raising the voltage. In the meantime the extra strain imposed upon the coil is apt to puncture the insulation, reducing the efficiency of the coil to a point where it is practically useless by reason of the windings that have been cut out, or ruin it entirely.

SOAP AS A FIRST AID TO THE INJURED.

Injured in this case does not necessarily mean the autoist himself, unless the liberal coating that is said to be best described "as matter out of place" may be considered an injury. But vibration and excessive jolting frequently bring about a leak in the unions of the fuel pipe that no amount of tightening suffices to eliminate. No matter how slight the drip, if it be constant, it means that fuel is being wasted faster than the engine is using it, and where there is any question as to the supply holding out a repair is imperative. The simplest, as well as the most efficient, way to accomplish this is to shut off the fuel at the tank, or at any point between the tank and the union to be operated upon. Unscrew the latter, wipe the threads, clean and smear them liberally with soap. A piece of soap dragged across the threads will serve to fill them, which is the object desired. Other substances than can be used to equal advantage for this purpose are graphite, stiff tallow, or red lead mixed with glycerine. In setting up piping it is customary to use red lead mixed with linseed oil, but as this sets with a cement-like hardness, its employment on the car is hardly to be recommended. Failing any of these materials, a tight wrapping of adhesive tape may serve as a temporary makeshift that will prevent further loss of the precious fluid.

BY
FRANCIS MILTOUN

THERE are three things demanded by touring automobilists: good accommodation for himself in the way of beds and baths (or at least hot water and plenty of it, hitherto a rarity in France), a good table (which need not be a country imitation of a Paris table d'hôte), and good garage accommodation for his machine. By this latter something more is meant than a backyard, uncovered shack where hens and chickens roost and all the débris of the establishment is thrown helter-skelter. France possesses, in general, all the hotel requirements of the automobilist en tour. This is not saying but that there are deficiencies here and there; but the country landlord in France tumbled to the fact, at a very early period, that there was a new class of traffic to be catered to and the accommodation that it demanded was something different from that which had been current before. Old court-yard inns, which had been dull and dreamy since coaching-days, were refurbished up, the old stables were torn down or rearranged to give plenty of light and air, and a clean, dry place was furnished where the lordly touring car or the eight-horse runabout of the really happy tourist could find shelter and *tout ce qu'il faut*.

The *garçon d'écurie* of other days comes to know the requirements of automobilists, and instead of filling nose-bags for horses he fetches and carries water and *essence* and gives you a hand here and there to speed you on your way—and doesn't expect a franc tip for every pail of water that he brings you, either. He'll take five sous and be thankful.

With the hotel accommodation itself the *patron* has become used to serving meals out of hours—it's astonishing how frequently one is a half an hour or an hour late for déjeuner when touring, not of course because anything was wrong with the automobile. Oh, nol but because one missed the road. Mostly the hotel *patron*, who often in the country-side of France is *chef* as well, sticks to his old system of feeding you the *plats* of the *pays*, but occasionally, in the large towns, as at Arles in the Bouches du Rhône, at Nantes in the Loire-Inférieure, or even at Rouen in Normandy, he plans unwisely and gives the same sort of fare that is known variously as a "table d'hôte" and "cuisine française" in Vienna, San Francisco, New York, or London. This is where he makes a mistake, and though he may catch a certain amount of quick-touring strangers who think their only safety lies in patronizing a "swell hotel" he is not as well advertised by his loving friends as the *patron* of the little inn around the corner whose clientèle is largely of the *commis-voyageur* class, and those travelers and tourists who know that his trail is that which leads to good cooking, eating, and drinking.

The general equipment of the French hotel before the advent

of the touring automobilist, and before "le tourisme" became popular in France was a dismal affair, and its only spontaneous gaiety was that awakened by its ample board with the good things of the table—food and drink alike—heaped high and served with a liberality and a local flavor which gave a new zest to each meal taken a dozen kilometers from where the last was eaten.

Evolution of the French Hotel.

Things don't move so slowly in France as is often supposed, though in the hotel line the high, coffin-like beds, with their overhung baldequins

and stuffy window hangings, have been slow enough in disappearing in some parts. Until very recently, and now they are not many, there has been an utter absence of a sitting, writing or reading-room in the country hotel in France. In the days of the poste-chaise and the malle-post travelers were of an exclusive and aristocratic class, and wealthy withal—the poor folk didn't travel, or if they did a "loge à pied" was good enough for them, and they furnished their own provender.

The hotel travelers had their own special apartments where they lived and lodged and ate apart, much as they did in their own homes. They had no need of a public sitting-room, and they summoned the patron to them to present his bill in person, and in general put on much side and made themselves conspicuous. For this reason no public rooms, save the *salle à manger*, have until recently been found in provincial hotels.

With no accessible or comfortable room in which to sit or write, most travelers in France stifle or freeze themselves, according to the season, in their heavily-curtained, brick or tiled-floored bedrooms or hang wearily about the corridors waiting for the hour of table-d'hôte at 7 or 7:30 o'clock. The *commis-voyageur* or the French commercial traveler, knows better how to utilize his time. He deposits his bags and traps in the hotel when he has finished "*les affaires*" and goes to a brilliantly-lighted, warm, comfortable café, which may or may not be a dependency of the hotel. Here he writes his letters, drinks his *apéritif* (his appetizer, which, by the way, is far behind a cocktail) of whatever of the sticky, varnishy concoctions he affects—a "*Pernod*," an "*Amer*," or a "*Dubonnet*," and is happy and genial through all of it and ready for his dinner when the time comes.

The last decade has brought many changes in the French provincial hotel. The bedrooms are considerably less stuffy than they used to be (this in summer, for they are no less frigid in winter). The heavy repp curtains at the windows are disappearing and hot water comes—when you order it—in sufficient quantity to at least remove the surface dirt of a dusty two hundred kilometers. Formerly you got a shaving mug full, and not very hot at that. Yes, things are looking up in the hotel line in France, and the automobile is the reason for it.

The above is simply a fair, unvarnished résumé of the state of affairs in the majority of small towns in

THE OLD GARÇON D'ECURIE.

France, where, by chance, one may be landed for the night; towns like Conches in Normandy, Noyon in Picardy, Agde in Pyrénées-Orientales or Gien on the upper Loire. In the neighboring towns, with no more pretense to importance often than themselves, the wave of progress has broken with much more force. At Moulins, on the Loire, in the Hôtel du Dauphin, with about all the modern improvements one can well add to an old fabric. The character and old-time charm is still there, but there is steam-heat and electricity everywhere, and a real bathroom with hot and cold running water. At Perpignan, a near neighbor of Agde, almost the same thing is true at the Hotel de la Poste, and the bedrooms are all "*chambres hygiéniques*"—which means that they have been installed according to the formula of the Touring Club de France, the most famous institution of the world for having the interests of tourists and the betterment of their accommodation at heart.

How the French Hotel Proprietor Is Being Educated.

The Touring Club de France has done a great thing in advocating the "*chambre hygiénique*," though with just how much favor it will be received by all classes of travelers is a question. Many will not care as to whether it is clean, healthful and bright or not, the *commis-voyageur* does not seem to have any very pronounced views on the subject; and most French travelers sleep with their windows and shutters tightly closed; thus the element of light and air is often not a consideration. Others will liken the bareness and plainness of these rooms to a prison-cell, or at all events to a cubicle in a hospital; but even this latter must be admitted to have some considerable advantages as a place of healthful repose. This, after all, is what one wants, or ought to want, and accordingly ought to be willing to forego something to get.

For twelve years the Touring Club de France has been struggling towards its ideal—the betterment of the accommodation offered all classes of travelers, and the universal adoption of the "*chambre hygiénique*" has been one of its fondest dreams.

The "*chambre hygiénique*" has white lacquered walls, severely plain "bent-wood" furniture and a brass or iron bedstead.

Throughout there is a lack of ornamentation which does not tend to a gracious home-like aspect, though it is a pity that the sleeping rooms of more Anglo-Saxon homes were not furnished on these simple lines rather than being crowded with the trumpery bric-a-brac, Japanese umbrellas and pampas plumes that one usually finds.

The Touring Club de France publishes explicit detailed directions as to how this novelty may be installed and distributes the information gratuitously to inn-keepers throughout the land. Furthermore, in many cases, it gives even more substantial assistance with regard to the outfitting. The ceilings, like the walls, are lacquered, and there are no mouldings or nobby gas fixtures to catch and harbor dust. The curtains at the windows are washable and so is the *descente de lit*, the little strip of carpet which covers the tiled floor in front of the bed. The *table-de-nuit* is a new idea of a useful article of furniture, and it, too, and the washstand, taboo the Eastlake, spindly-railed decorations under which a suffering people labored under Louis Philippe, Queen Victoria and Andy Johnson.

All this does not preclude an artistic ensemble by any means, though it takes some considerable influence to move the masses on such points, even in France, for with all their natural artistic sense the French are firm adherents of such conventions as have been instilled into them since the horse-hair and plush horrors of the Citizen-King.

The *cheminée*, or fireplace, plays a grand rôle in the ventilation of a sleeping apartment, and where one exists, says the Touring Club formula, it should be allowed to perform the functions of drawing a *courant d'air* from an open window. The table tops, etc., throughout are of marble, real or artificial, and all bed hangings are abolished.

As for the French beds themselves something new was manifestly demanded to replace the stuffy upholsterings and cabinet

work of those abominations which were the despair of the lover of airiness and cleanliness. An iron and brass model of a bedstead has been approved by the T. C. F. It has no ridges, ledges or crevices to harbor dust and things. In France seldom, if ever, were the beds unclean, except for the soil incident to ages; but the thick stuffed *paille* of feathers, or more often wool, was certainly not hygiénique, no matter how frequently it was turned and pounded into a semblance of fluffiness.

Something soft to recline upon was necessary, no doubt, but an animal product is about the worst that could have been adopted. Cotton-waste, pine-shavings, corn-husks and sea-weed are all in use in the beds of France and possibly some sort of a combination of these things is what is required, but a sweeping change is due to be made from general existing conditions.

Again the Touring Club suggests that the *paille* and mattress be enveloped in a white or ecru sack, or covering, which may be readily lifted and washed. The bed-clothes, too, comport with the march of progress, and no one who cares a whit for his health and comfort thinks of sleeping under a heavy padded quilt, such as our grandmothers and great-grandmothers used to delight in making. What awful and depressing things they were, to be sure!

Now the up-to-date *hotelier* in France has his *couvertures*, light, warm and washable, and the great eider-down puffs (which the French, by some extraordinary process of reasoning, call "*couvres-pieds américains*") are covered with a slip which is also washable, instead of a Japanese silk skin which soon becomes torn and, what is left of it, distinctly greasy.

The size of the wash-basin, and its accompanying water-jug even, is prescribed. This is a move in the right direction. The chocolate sets sold by department stores, at forty-nine cents for a little pitcher, a great cup and a tiny sugar bowl, are a very good illustration of what the appurtenances of a French hotel washstand used to be.

As for the cleaning of a sleeping room such as this, it is a very simple matter. No more general turnings out, such as the English maid-of-all-work delights in, if only for the discomfort it causes others; no more of the spring cleanings of New England housewives, which are equally disconcerting; a simple washing off by soap and scrubbing brush, and a drying off with a cloth is all that is required. An able seaman, who is usually very well versed in this sort of scrubbing, could do it quite as well as any *bonne à tout faire* that ever wielded a broom or a mop, though it must not be forgotten that the *femme de chambre* in France to-day is usually a *garçon de chambre*.

Since it is pleasanter to say good than ill of things, one may now turn to the glad side of the country hotels of France and be thankful, at any rate, that nothing quite so foul or disgusting is ever seen in a French inn, as the supply of carpet slippers which the English inn-keeper keeps on hand for the general use of the none too fastidious English bagman who patronizes his establishment and drinks whiskey and soda with his meals. The French *commis-voyageur* may have his bad habits (straining his soup through his whiskers and guzzling his food aloud are two of them), but nothing that one sees in full view is quite as bad as that almost universal custom of his English confrère.

The foregoing outline has been made as brief as possible, and that a considerable effort has been made on the part of concurring hotel keepers in France to meet modern exigencies at least half way is the best proof that the fast-growing automobile clientele is not being ignored. As the report of the Touring Club de France has it:

"*La propreté de la chambre et du lit est le premier et le minimum des desiderata auxquels nous avons droit.*" (Cleanliness of the room and the bed is the first and the minimum desiderata to which we have a right.)

The Touring Club de France has not stopped there: it has furnished freely and gratuitously plans and projects for the installation of modern sanitary arrangements, and has even been known to establish and pay for a model accessory of this sort where it was badly needed and where it was thought to be a

good example to others. All these innovations—practically all brought about by the advent of the automobile—scattered though they be all up and down France, have had an undeniable influence for the better on the hotel industry here. Given two hotels, one with these modernities and the other without, and the automobilist and other travelers, too, will patronize the former if they only know which is which.

Twelve hundred hotels all over "la belle France" have given adherence to these new ideas of the Touring Club by taking its admonitions to heart. All this is set out in the Touring Club's "Annuaire" or Hotel List with great completeness, and the Automobile Club de France in its "Annuaire de Route" gives similar information, rather less completely, though rather ingeniously. Here one finds a little silhouetted knife and fork and an old-fashioned bedstead, indicating a good table and good beds. A good idea this which all guide-book makers might adopt, with a still further elaboration, to the benefit of their clientèle.

French Guide Books Give Useful Hints.

The Guide-Michelin, issued by the great pneumatic tire manufacturers of Clermont-Ferrand, do the thing with considerably more completeness, all by means of little typographical signs and indices—which look Greek to the uninitiated, but which are a veritable way-about-courier to

and S. de B. (salle de bains) a bathroom, and W. C. the obvious thing, with this in addition, when it deserves it, *bien tenu et perfectionné dernièrement*—this really means something in France.

The initials T. C. F., A. C. F. and A. G. A. indicate that the house is affiliated or endorsed by the Touring Club de France, the Automobile Club de France, or the Association Générale Automobile, and if you are a member of the first-named (write to the headquarters, 65 Avenue de la Grande-Armée, Paris, for particulars as to membership, the fees of which are nominal) as like as not you get a discount of ten per cent. from your bill for having favored the hotel with your patronage. This is enough to pay one's tips.

One notes the panels of these great touring organizations all over France, usually posted prominently on the façade of the hotel, and with these as a landmark, and any of the three guides or route books before mentioned to place their location, one is bound to know beforehand just what one may expect to find and what one is likely to have to pay for it.

There are three classes of country hotels in France, not counting the purely resort hotels, patronized by the automobilist en tour; the frankly country, market town hotel, such as you find at St. Remy-en-Provence, Auray, in Brittany, or Louviers, in Normandy, where you literally stable your machine along with the market wagons, country

IN PROVENCE.

THE CHEVAL BLANC, ANGERS.
TYPES OF FRENCH COUNTRY INNS.

ON THE SEINE.

those who know their real meaning. One, two or three stars (* ** ***) shows that the price which one may expect to pay per day (*tout compris*) is nine or less, eleven, or thirteen or more francs. If wine is not included in the price (and very seldom is it not) the letters *v. n. c.* (*vin non compris*) appear. This is all one needs to know as to prices. Now for the rest: A little square black spot means a dark room for photographers, a figure 6, 8 or 10 in a little square indicates that there is ample garage accommodation for the prescribed number of automobiles, a sort of capital U that there is a fosse or inspection pit, and "Ess" and "H" mean that *essence* and *huile* can be had on the premises (gasoline and oil). These latter commodities will cost you something more than they will at the grocer's around the corner (don't forget that, Mr. Tourist, if you are running a high-powered car with a voracious appetite). On the other hand, the hotel proprietor expects you to "buy something" to help him out on the expenses of the up-keep of his free garage. Buy ten litres of *essence*, if you like, or a two litre bidon of *huile*; he will be satisfied. Finally a jagged electric-spark-looking sort of a mark indicates that accumulators may be charged on the premises.

They go further than this, too, when it comes to the hotel accommodation itself. Ch. hyg. means "*chambres hygiéniques*,"

carts and what not. Then there are the hotels of the *sous-préfectures*, like Evreux, Bourges or Poitiers, where, if they are somewhat pompous, the hotels are still countrified and have not a suspicion of Paris about them, either with respect to their cuisine or their appointments.

Then there are the *grands hôtels* of the cities, such as Marseilles, Bordeaux or Nantes, where one pays from twelve to fifteen francs a day—*v. n. c.* in most cases.

Finally there are the "resort hotels" of Trouville, Biarritz, Nice or Aix-les-Bains, which are ultra-everything and where one pays anything one likes, wholly unattractive, so far as local color or character goes, either in their appointments or their cooking, being rank imitations of the real thing at Paris. *Vin* is never *compris* and you pay dear for what you do buy, and a franc and a quarter or a franc and a half for a bottle of *vichy* which you buy elsewhere for eighty centimes.

The two first-mentioned classes of establishments are the *vrais hôtels du pays* and those of the last class are as like as two peas in a pod and frankly reminiscent of the Ritz in Paris, the Carleton in London or the latest skyscraping palace hotel of New York, at least so far as go the conventionalities, fripperies and the deadly staleness of full-dress dinners and teas on the terrace or in the palm room.

The best provincial hotel in France, all things considered, is the Cheval Blanc at Angers, a successor to a sixteenth century inn on the same site, with some modernities, but still possessed of a character which is distinguished, a comfort which is remarkable, and an excellence of cuisine which is a marvel.

Angers is a little beyond the beaten track of tourists in the chateaux country, but it is worth running down to just to put in a day at the Cheval Blanc and see how well a provincial hotel can be run and how wholly attractive it can be. Saumur, near by, runs Angers a close second with its Hôtel Budan. Champagne's only real rival comes from Saumur, and when you have stabled your automobile in the really luxurious little paved courtyard garage you will enjoy a bottle of it with your dinner. It won't cost you over five or six francs for the best.

Tours, in the heart of the châteaux country, has a magnificent establishment, the Hôtel de l'Univers, whose proprietor is progressive enough to keep a fleet of automobiles for hire to tourists who do not bring their own. The

Hôtel de l'Univers is to all intents and purposes a "resort hotel," though Tours is neither a watering place, a mountain resort or a gambling hell. This classification, however, puts the hotel out of the category of French provincial hotels. Its garage is quite the most palatial thing of its kind to be found in France and appears to have accommodation for half a hundred machines. The feeding here is not as good as the rest; one can do much better at a little *commis-voyageur* hotel (du Croissant), on a back street opposite the post-office; but not catering especially for automobilists, they cannot house more than a couple at a time, and one often has to board the machine out for the night.

Nantes, at the embouchure of the Loire, a one-time dignified provincial capital, was praised by a century-old traveler for its Hôtel de France. The hotel is still there and the date over its portal is written large—1796—but within a twelvemonth it has fallen from its previous character and become a pseudo de luxe hotel with a restaurant where you—being an automobilist—are supposed to eat and pay fifteen prices for everything. There is a "lounge" and no end of gold-braided lackeys hanging around doing nothing but getting in your way. Nantes needs nothing of this kind; it is not a city of a million inhabitants, and is not a resort, but merely a busy port and manufacturing ville, enterprising, substantial and wealthy, no doubt; but there is, as before said, no call for such a fell blow as has spoiled the Hôtel de France of other days.

(To be continued.)

FRENCH MARINE MOTOR KEROSENE CONTEST.

The competition organized by the Automobile Club of France for marine motors using kerosene as fuel, and intended for service in the navy, has just been brought to a close. The motor Cazes gained first prize, and will be bought by the Government. The Mietz & Weiss motor will also enter the navy. A new competition will shortly be organized by the Minister of Marine for kerosene motors, and next year an important competition for kerosene-driven motor boats to be used in protecting fishing craft will be held.

Automobile instruction will be specialized in the new *Arts et Métiers* college to be built near Paris. A three-year course will provide instruction in various arts and trades; the fourth year's course will be devoted especially to automobile construction and electricity. The college will cost \$1,200,000.

THE AUTOMOBILE CALENDAR. AMERICAN.

Shows.

- Jan. 28-Feb. 2.—Washington (D. C.) Automobile Show, Dupont Garage, Washington Automobile Dealers' Ass'n.
 Feb. 2-9.....—Chicago Automobile Show, Coliseum and First Regiment Armory. S. A. Miles, manager, 7 E. 42d Street, New York City.
 Feb. 11-16.....—Detroit, Mich., Sixth Annual Automobile Show, Light Guard Armory, Tri-State Automobile and Sporting Goods Ass'n. E. E. McMasters, mgr.
 Feb. 18-23.....—Fifth Annual Automobile Show, Buffalo, Convention Hall. D. H. Lewis, manager, Teck Building.
 Feb. 18-23.....—Cleveland Automobile Show, Cleveland Automobile Trade Association.
 Feb.—San Francisco, Golden Gate Park Skating Rink. Automobile Show. Dealers' Association and Automobile Club of California.
 Feb. 25-Mar. 2.—Portland, Me., Second Annual Automobile and Power Boat Show, The Auditorium.
 March 2-9.....—Chicago, Second Annual Power Boat Show, Seventh Regiment Armory. W. C. Andrews, manager, 19 E. Huron street.
 March 2-9.....—Automobile Show. First Regiment Armory. Minneapolis Automobile Dealers' Association.
 March 4-10.....—Kansas City, Mo., First Annual Automobile Show, Convention Hall. Frank L. Woodward, manager, Willis Wood Theatre Building.
 March 9-16.....—Boston Automobile Show, Mechanics' Hall and Horticultural Hall, Boston Automobile Dealers' Association. Chester I. Campbell, manager.
 March 13-16....—Second Annual Automobile Show, Omaha Dealers' Association. Auditorium Bldg. T. Gillian, mgr.
 March 18-23....—Providence (R. I.) Automobile and Power Boat Show, Infantry Hall. F. M. Prescott, manager.
 April 1-6.....—St. Louis, Mo., Automobile Show, Jai Alai Building, St. Louis Automobile Dealers' Association.
 April 6-13.....—Montreal, Canada, Second International Automobile and Sportsman's Exhibition. R. M. Jaffray, manager, 309 W. Notre Dame street.
 April 8-13.....—Pittsburg, Pa., First Annual Show of the Pittsburg Automobile Dealers' Association, Duquesne Garden.

Race Meets, Hill Climbs, etc.

- Jan. 22-26.....—Ormond-Daytona (Florida) International Race Meet, Florida East Coast Automobile Association.

Motor Boat Races.

- Jan. 29-Feb. 1.—Palm Beach, Fla., Annual Races of the Palm Beach Power Boat Association.
 Sept. 2-6.....—Jamestown (Va.) Exposition, Motor Boat Races.

FOREIGN.

Shows.

- Jan. 25-Feb. 2.—Liverpool Motor Show, Tournament Hall.
 Feb. 1-9.....—London, Crystal Palace Motor Show.
 Feb. 16.....—Automobile Show, at Turin, Italy.
 March 7-16.....—London, Olympia Commercial Vehicle and Motor Boat Show.
 April 6-13.....—London, Agricultural Hall Motor Show.
 May 1-15.....—Madrid, Spain, Automobile Exhibition, Palace of Fine Arts, Royal Automobile Club of Madrid.
 May 15-26.....—Third Annual Swiss Automobile Show, Zurich.

Race Meets, Hill Climbs, etc.

- Feb. 23-27.....—Volturette Contest, Automobile Club of Italy.
 March 20-27....—Nice (France) Automobile Week.
 April 1-15.....—Spring Wheel Competition.
 April 21.....—Targa Florio Tour (Sicily), Auto Club of Milan.
 April 25-28.....—Touring Contest, Automobile Club of Touraine.
 April 28.....—Chateau Thiers Hill Climb.
 May 24-27.....—Volturette Contest, Automobile Club of Austria.
 May 29-June 1.—Irish Automobile Club Reliability Trials.
 June 3-12.....—Herkomer Cup, Automobile Club of Bavaria.
 June 14.....—German Emperor's Cup, Taunus Circuit, Imperial Automobile Club.
 June 24-29.....—Scottish Reliability Trial, Scottish Automobile Club.
 June 25-July 8.—Grand Prix, Automobile Club of France. (Exact date to be decided upon.)
 Aug. 11-20.....—Coup d'Auvergne, France.
 Aug. 18-22.....—Ardennes Circuit (Belgium) and Coupe de Liège kerke.

MIDWINTER ACTIVITIES OF THE CLUBS.

Characteristics of the Proposed Illinois Auto Law.

CHICAGO, Jan. 21.—Throughout Illinois automobilists are lining up to support the bill introduced into the State Senate by Senator Humphrey, and will make a hard fight to put the measure through. Two years ago a similar law was passed by the Legislature and vetoed by Governor Deneen. This session it is hoped to prove to the Governor that public sentiment is favorable to fair play for automobilists. The bill was drawn up by Secretary Sidney Gorham, of the Chicago Automobile Club, and will receive the backing of that powerful body and Chicago Motor Club, which, though only recently formed, has achieved an enviable reputation for energy and push.

The most important features of the Humphrey bill are the clauses fixing speed limits throughout the State at twenty miles per hour in the country districts, fifteen miles for the cities, and ten miles per hour in congested business centers; registration by the Secretary of State, who on payment of a \$2 fee will issue numbers and tags good in any part of the State. Speed limits in municipalities less than the marks fixed by law and local licenses and numbers are abolished. It is provided that every car shall carry for from one hour after sunset to one hour before sunrise at least two lighted lamps showing white lights visible at least 200 feet, and one red light in the rear. Cars must be provided with good brakes and a bell, horn, or other signaling device.

Another clause provides that any person driving a motor vehicle in a race on a public highway shall, upon conviction, be fined a sum not exceeding \$50, and still another clause provides that automobilists shall, at request, or upon signal by holding up the hand or otherwise, from a person riding or driving a horse or horses in the opposite direction, cause the motor vehicle to stop and remain stationary, and shall, if requested, stop the engine of said motor vehicle so long as may be necessary to allow said horse or horses to pass. Special registration of professional chauffeurs is provided for, the fee for same being set at one dollar.

Friday Evenings at Long Island Automobile Club.

BROOKLYN, N. Y., Jan. 22.—There is always "something doing" on Friday evening at the home of the Long Island Automobile Club. The most recent announcement of the entertainment committee includes the following: Friday evening, January 25, exhibition of 1907 cars—Ford, Thomas and Stevens-Duryea—music and refreshments; Friday evening, February 8, smoker and vaudeville show; Friday evening, February 15, exhibition of 1907 cars—Oldsmobile, Matheson and Dragon—music and refreshments; Friday evening, March 1, smoke talk, etc., and on this occasion A. R. Pardington, vice-president and general manager of the Long Island Motor Parkway, will tell all about that notable enterprise, and the progress that is being made; Friday evening, March 15, vaudeville show. The regular monthly meeting will be held Wednesday evening, January 30.

Theft Rouses the Grand Rapids A. C. to Action.

GRAND RAPIDS, MICH., Jan. 21.—Recent cases of aggravated automobile thefts and slashing of tires have awakened the Grand Rapids Automobile Club to action, and the latter has now determined to put a stop to the practices. The first step in the agitation is the offering of a reward of \$50 for the persons who stole the car of W. S. Gunn from in front of his residence and later deserted it. The large number of cars in Grand Rapids has made it exceedingly difficult to locate a stolen one, but business men and automobile owners alike are determined that the marauders shall be captured and summarily dealt with.

California Claims the Pioneer Woman's Auto Club.

SAN FRANCISCO, Jan. 16.—The recent organization of a women's automobile club in Philadelphia has awakened public attention to the fact that California, and this city in particular, claims priority in the forming of an auto club composed entirely of the fair sex. The president of the California Woman's Automobile Club, Mrs. J. A. Marsh, to support the contention, makes public the history of the organization, as follows:

"The club was organized on October 4, 1905, at my home. After the second meeting we secured quarters in the California Women's Club, where the meetings were held thereafter. We had exceedingly pleasant rooms and were thinking seriously of securing a building of our own when proceedings came to an abrupt stop in April of this year, in consequence of the great disaster which overtook our city. The first run of the club was to San José. There was a large attendance, and at that meeting the membership was almost doubled. The club had also under consideration the scheme of short picnic runs that could be held in a day.

"For the present the officers of the club are preparing to hold the annual meeting in January. At that time we shall elect officers for the year and lay plans for an active season. First there will be a series of luncheons at which papers will be read. These papers are to be prepared by members of the club and some of the well known men authorities in the sport. The men will not, however, be present, as the club bars the sterner sex from all its meetings. These luncheons will occupy the time between the annual meeting and the spring-time, when the roads will again be open for driving. Then will come short runs of a day's duration until the latter part of May, when the officers plan to conduct a race meet, at which only women will be permitted to compete, and gymkhana games. The race meeting is to be followed by the annual vacation outing. This will occupy from one to two weeks. It will consist of a tour of the State. One of the objects of the run will be the establishing of clubs in the larger cities visited.

"If the race meet in the spring is a success another will be held in the fall. While the members are planning and taking part in the pleasures of the pastime they will not be forgetful of the hard work that is a part of the life of the club. At the monthly business meeting the members will plan for the improvement of the roads and for obtaining legislation toward that end. The matter of legislation is in the hands of the Automobile Club of California, but our organization is going to do its part in helping the work and in seeing to it that the laws are strictly observed."

Benefits of Organization Shown by Cleveland A. C.

CLEVELAND, O., Jan. 21.—Lack of enthusiasm which has marked club work in Cleveland in previous years is undergoing a radical change. One of the best evidences of this is the program mapped out by the Cleveland Automobile Club for the new year, and the great interest being manifested in the work as evidenced by the attendance at the smoker recently given by the club at the Hollenden Hotel. A goodly proportion of the membership and a number of invited guests were present. Addresses were made by a number of prominent automobilists. The trend of the arguments pointed to the great enlargement of the enjoyments of autoing which could be made possible through organization of those interested.

W. P. Sholes, president of the club, sounded the keynote when he said that the success of all movements in the busi-

ness world were due to organization, system, and combination of effort. While astonishing progress has been made in the development of means of locomotion, the subject of road improvement had received little attention in this portion of the country, especially in Ohio. Not only in road conditions, but in laws governing the use of automobiles, is the Buckeye State deficient. The present automobile law is crude, insufficient, and narrow as compared with those in force in other States. Local ordinances in many communities are conflicting and embarrassing to local people as well as to tourists. In a number of portions of the State there have been efforts to improve roads, but the work has been spasmodic, and there has been a lack of uniformity.

In brief, he thought it the duty of the Cleveland Club to lead in the movement to secure better roads and better laws. To accomplish this the club must be made stronger. At present it has about 500 members, but he thought this was altogether too small, considering the fact that there are more than 3,000 owners in the city. He pointed out that the club had accomplished much good in the past, and had large plans for the future. He stated that about \$10,000 had been pledged for the building of a stretch of model road east from Cleveland, and that the success of the movement originated by the club was now assured. The club has stimulated the organization of the Ohio State Automobile Association, and has aided in the formation of clubs in some of the largest cities of the State. Cincinnati, Columbus, Springfield, Ashtabula, Akron, Elyria, and several other towns now have good live clubs, while the Toledo and Dayton clubs promise to reorganize and assist with the work. He thought that a membership of 3,000 ought to be secured for the State organization without much difficulty.

During the Cleveland automobile show the Cleveland Automobile Club will hold open house in a portion of the Central Armory, where the show will be held. A suite of rooms off from the main exhibition hall has been set aside for the club, and it will be fitted with every convenience and comfort for the entertainment of visiting automobilists. Everyone will be welcome. There is talk that the club may decide to hold a banquet, to which all visiting automobilists and local owners will be invited. The club is sparing no legitimate means to build up its membership to a very high mark, and it is believed that these entertainments will have the desired result.

Buffalo's Plan for Chauffeur Bureau Outlined.

BUFFALO, N. Y., Jan. 21.—A plan, which it is hoped will do much toward effecting a satisfactory solution of the chauffeur problem, is being fathered by the Automobile Club of Buffalo. It possesses the merit of being comparatively simple in theory and one that is very easily carried out. Secretary Dai H. Lewis of the club has written the following letter, which fully explains the plan in detail to the secretaries of all the automobile clubs in the country:

"It has been suggested that if the various automobile clubs organized a chauffeurs' reference and employment bureau for the protection of members and also with the belief that it will inure to the benefit of the best class of chauffeurs by segregating them from the immoral and intemperate class; and it will also assist chauffeurs to obtain employment with the best employers, *i.e.*, members of the various automobile clubs.

"It is believed that if all the automobile clubs throughout the country will take up this serious question aggressively the morale of chauffeurs will be greatly increased and the chauffeurs' troubles will be largely minimized."

American Auto Tourists File a Protest.

NEW YORK, Jan. 22.—On the recommendation of the bureau of tours of the Automobile Club of America the board of governors of the club has passed the following resolutions protesting against the expensive crating of automobiles for foreign shipment required

by transatlantic steamship companies, a matter that has been costing American autoists several thousand dollars annually:

Whereas, many members of the Automobile Club of America and owners of automobiles are desirous of taking cars to and from Europe; and whereas,

The expense of doing this is very great and such expense is increased by reason of the cost of crating, the drayage to and from the steamship, the use of cranes and lighterage; and whereas,

It is desirable that this expense should be reduced as much as possible; and whereas,

Automobiles are carried in Europe without being crated, it is Resolved, That this club call the attention of the different steamship lines plying between this country and Europe to the fact that in its opinion the crating of automobiles, the charge for the use of hoisting apparatus and lighterage are entirely unnecessary and that the steamship companies be requested to make arrangements by which they will carry automobiles across the Atlantic without crating.

A. C. of Philadelphia Elects a New Treasurer.

PHILADELPHIA, Jan. 22.—At last week's meeting of the Automobile Club of Philadelphia, the vacancy in the treasurership and in the board of governors caused by the resignation of J. Maxwell Bullock was filled by the appointment of Jacob J. Leeds. H. Bartol Brazier, secretary, and G. L. Gundlfinger, assistant, were continued in office for another term. Isaac Starr, Jr., chairman of the committee appointed to establish a legal department, whereby all members who run afoul of the authorities may receive legal assistance and advice, was given *carte blanche* to complete arrangements therefor.

CLUB DOINGS IN GENERAL.

PHILADELPHIA.—The Quaker City Motor Club is considering the project of a hill climb for Decoration Day, which will be of national importance, open to all owners, dealers and manufacturers. There are a number of suitable hill courses in the suburbs, one of which will be selected.

UTICA, N. Y.—Officers elected at the annual meeting of the Utica Automobile Club are as follows: President, George A. Frisbie; first vice-president, F. W. Sessions; second vice-president, R. B. Billings; secretary-treasurer, Robert M. Hunt. The club now has a membership of seventy-six.

BINGHAMTON, N. Y.—Fully twenty-five members of the Binghamton Automobile Club attended the auto show in Madison Square Garden last week. The club is particularly active this winter, and is mapping out a season's work for the coming summer that will give the organization great prominence in the work of highway improvement.

NEW YORK.—President Samuel B. Stevens, of the New York Motor Club, has appointed a committee, consisting of Prof. F. R. Hutton, Robert Lee Morrell, A. H. Rutherford, T. F. Moore and A. Schwalbach, to investigate the proposed automobile speedway along the line of the Catskill reservoir and report upon same with a view to indorsement by the club.

NEW YORK.—Thirty-two new members have been elected to membership in the Motor Boat Club of America since December 1. The club is considering the project of a long-distance race from New York to the Jamestown Exposition, by the outside course, at the time of the club's annual cruise to Hampton Roads, arriving there in time to participate in the motor boat carnival which opens September 2.

ST. LOUIS.—Speaking for the St. Louis Automobile Club, Secretary Roy F. Britton says that the organization will not go into the courts to test the validity of the present ordinance restricting the speed of autos to eight miles per hour in that city. The club believes that nothing can be gained by fighting the law, but believes that a more liberal ordinance should be enacted, raising the speed limit in driveways of the public parks to fifteen miles per hour.

THE HARROUN RECORD SEEKER AT ORMOND.

Has 8-cylinder air-cooled motor, weighs about 250 pounds, and has been successfully tried out on the Ormond-Daytona course.

CURTISS 8-CYL. MOTORCYCLE ALSO WANTS RECORDS.

Said to be the largest and most powerful machine of its type [in existence—40 horsepower. This week at the Ormond races.

ON THE SEA-SWEPT SANDS AT ORMOND

By A. G. BATCHELDER.

HOTEL ORMOND, Jan. 22.—There won't be much of a story to tell of the doings this week on Florida's famous stretch of sand, and this a pity, for the weather is perfection, the program well planned, the officials experienced, and all indications pointed to a successful racing innings.

The reasons are several and the principal one is the presence of the Stanley steam sprinter, which appears certain to lower its world's mark of :28 1-5 at the first favorable opportunity. This abnormal auto racing craft qualifies for the game under liberal interpretation of the rules, but its superiority over the gasoline flyers stops at a distance under five miles. Of course the short distance performances of such a vehicle should rank second in worth to the prolonged high speed traveling of cars quickly converted to general use, but the more startling dashes of this steam space annihilator command greater attention in the daily press. Hence the gasoline makers have practically left the Ormond-Daytona meet to the Stanley and reserved their competition to events wherein sprints will not detract from the more valuable middle and long-distance struggles which call for speed provenly coupled with the characteristics of endurance.

Even the Darracq contingent, which a year ago conquered steam in the two-mile-a-minute star race, seems to have deserted the field after entering. At this writing the absence of Wagner, the Vanderbilt winner, looks probable, and though there may be trouble for him and his company with the racing authorities, dispatches involving the Florida East Coast Automobile Association, the American Darracq Company, and Chairman Thompson have not resulted in the assurance of the presence of the noted Frenchman in the 100-mile race scheduled for Friday.

There is available a fairly large number of touring cars of various kinds, and with these and the steam cars a program will be patched out to accompany the mile steam sprints, which, it is predicted, will be faster than 130 miles per hour. Monday Marriott did :38 3-5 without much effort, and the equanimity with which it was received contrasted vastly with the enthusiasm created by W. K. Vanderbilt's :39 of only two years ago.

January dates for a Florida meet are mighty inconvenient for many in the automobile trade, and both entry list and attendance are suffering from this fact. The Chicago show too closely follows the Madison Square Garden exhibition, and

FERRYING THE OLDSMOBILE FLORIDA PATHFINDER ACROSS THE ALTAMAHA RIVER, A CHARACTERISTIC GEORGIA STREAM.

FINDING WHAT PONCE DE LEON SOUGHT AT ST. AUGUSTINE.

those who must attend both cannot be lured to the "Land of Flowers" for such a brief stay, especially when for three years previous the weather has been of the most uncertain variety.

Up to the present time no records have been broken, as the course for the past two days was not in first-class condition, numerous small gullies having been left in the sand by the receding tides. In to-day's events E. B. Blakeley, a Harvard student, driving a Mercedes car, won the five-mile race for all classes of cars from a standing start. The other starters were: R. A. McCready, 20-horsepower Rolls-Royce, and H. E. Rogers, 25-horsepower Stanley. Blakely got away in the lead, but Rogers got by him in the first mile and had a lead of nearly a mile, which he held for nearly four miles, when his steam seemed to fail and Blakely and McCready passed him.

The Stanley "Bug," driven by Fred Marriott, and Capt. Hutton's 20-horsepower Rolls-Royce, piloted by R. A. McCready, were the only starters in the five-mile flying start record race. The steamer won by a mile or more.

A slow race for stock cars for a quarter of a mile on the high gear had seven starters. W. A. Adriance, in a Stevens-

Duryea car, won in 1:13; Walter C. Baker, Peerless car, was second, and Ralph Owen, Oldsmobile, third. The cars carried a full quota of official observers.

In the mile contest, with flying start, for stock touring cars, fully equipped and carrying four passengers of an average weight of 150 pounds, there were three starters: Frank Durbin, 20-horsepower Stanley; G. D. W. Rose, 30-horsepower Stoddard-Dayton, and R. A. McCready, 20-horsepower Rolls-Royce. The Stanley won easily by a furlong from McCready in 53.2-5 seconds, the same distance separating McCready from Rose.

Summaries, First Day, January 21.

ONE MILE RECORD TRIAL.

- Stanley Steamer, 30-h.p.; driver, Fred Marriott.....38 4-5 sec.
- Curtis Motorcycle, rider, George Curtis.....1:04 4-5
- Stanley Steamer, 30-h.p.; driver, L. F. Baldwin.....Did not finish.

Summaries, Second Day, January 22.

FIVE MILES, STANDING START, FOR ALL CLASSES OF CARS, AMATEURS TO DRIVE.

- 1. American Mercedes, 70-h.p.; driver, Edward Blakely.....4:26
- 2. Rolls-Royce, 20-h.p.; driver, R. A. McCready.....
- 3. Stanley Steamer, 30-h.p.; driver, H. E. Rogers....Did not finish.

FIVE MILES, OPEN, FLYING START, FOR WORLD'S CHAMPIONSHIP RECORDS.

- 1. Stanley Steamer, 30-h.p.; driver, Fred Marriott.....3:44 4-5
- 2. Rolls-Royce, 20-h.p.; driver, R. A. McCready.....4:52 4-5
(Record, 2:47 1-5, made by Marriott last year.)

MILE-A-MINUTE, FLYING START, FOR TOURING CARS, FOR THE AMERICAN CHAMPIONSHIP.

- 1. Stanley Steamer, 20-h.p.; driver, Frank Durbin.....:53 2-5
- 2. Rolls-Royce, 20-h.p.; driver, R. A. McCready.....1:09 2-5
- 3. Stoddard-Dayton, 30-h.p.; driver, E. D. W. Rose.....

SLOW RACE, QUARTER MILE, FOR TOURING CARS, ON HIGH GEAR.

- 1. Stevens-Duryea, 30-h.p.; driver, W. A. Adriance.....1:13
- 2. Peerless, —h.p.; driver, Walter C. Baker.....
- 3. Oldsmobile, 40-h.p.; Ralph Owen.....

FIVE MILE FLYING START MATCH RACE.

- 1. Stanley Steamer, 30-h.p.; driver, H. E. Rogers.....3:54 4-5
- 2. American Mercedes, 70-h.p.; driver, Edward Blakely....

ONE MILE STOCK TOURING CARS.

- 1. Oldsmobile Pathfinder, 35-h.p.; driver, Ralph Owen.....1:12
- 2. Winton, 30-h.p.; driver, Asa Palne
- 3. Wavne, 30-h.p.; driver, A. L. Kull

RECEPTION OF THE OLDSMOBILE FLORIDA PATHFINDER AT HOTEL ORMOND, ON THE CONCLUSION OF ITS HISTORIC TRIP.

HOTCHKISS TAKES A. A. A HELM.

(Continued from page 182.)

road appropriations are from the States, as the result of local agitation, and future work in this direction must be done largely through State associations and clubs. This work is, however, the most far-reaching of all work attempted by automobile bodies, and as a part of it, a great central committee representing most of the States can, by co-operation and counsel, accomplish much.

It is suggested that there are already too many good roads committees. Perhaps so. Yet even a central sub-committee, composed of representatives of national organizations only, cannot accomplish in a year what a State committee, familiar with local conditions, can in a month. Decentralization, rather than centralization, is necessary to the good-roads movement, and this association will do well if it leaves this matter largely with the States.

The recent enthusiastic launching of the Long Island Motor Parkway project marks an era in road development. Some suggest that it means that, as motor vehicles become larger and more powerful, they will, like the older locomotive, be driven to roads of their own, and the early history of the steam car on the public highways be repeated. Vital differences between the locomotive and the motor car, together with the increasing acquiescence of the public in their operation on the common roadways, preclude such a result. However, that, side by side with the highways, especially in populous districts, will be constructed private roads for motor vehicles is no longer a prophesy; no more is the statement that, before many years have passed, they will be constructed not by enthusiasts, but purely as an investment. The association is to be congratulated on the activities of many of its prominent members in the pioneer movement of this kind and, while not actively participating in any private work, should co-operate with members desiring to promote or construct such motor highways to the limit of its power. In the division of the associations work this new branch naturally falls within the sphere of the good-roads board, and to such board should be assigned.

Touring.—How far the association should assume charge of a tour, which is, in effect, a trade contest, is a difficult question. The very conditions surrounding a struggle for the best advertisement make successful management doubtful from the start. Criticism is certain; all of it loud voiced, much of it trivial, and, doubtless, a deal of it unwarranted. It is hard to say, however, that the association should not hereafter regulate the contest for the Gilded trophy, so generously given into its custody, and the touring board will doubtless make new rules and seek again the impossible, i. e., the award of the trophy to the best tourist, when the contestants are largely professionals and the real tourist takes the other road.

The touring board, however, has work before it of a broader, better kind. While governmental conditions and the absence of nearby frontiers in the United States present far different facts than those noted by tourists in France, as our roads improve and State laws become more uniform, the association should perform for the touring motorist—and who in the coming years will not be one?—what the Touring Club of France does in the great European republic, in fact, on the continent at large. Such a work is not to be done in a day or even a decade. But a beginning can be made now.

It may be done in a very simple way. Next to roads, tourists want road signs. The touring board should at once adopt a simple metal distance sign and a code of roadside directions similar to, though not necessarily as complex, as those in use in France, and when adopted furnish a set of such samples to each State association and club, with a circular indicating the territory and roads allotted to each, as well as the cost of the signs, and requesting immediate action. Moreover, if the treasury warrants, the association will find no saner use for its funds than by proportionate appropriations toward the road-sign expense of its affiliated bodies.

This, however, should be but the beginning. There should be established in the secretary's office, under the general supervision of the touring committee, a bureau of touring information, by which should be collected all published touring information as to roads, laws, hotels, maps and the like, which information should be given out to a member on request, and, if funds warrant, later published on route cards. Here the member in doubt as to the best road, in search of information as to roads improved or in process of improvement, seeking to purchase the best maps of a given territory, asking suggestions as to hotels, and, above all, desiring information as to speed restrictions and registration requirements, should be able promptly and without expense to learn. Little can, perhaps, be done the first season. But let the work be begun, and, if properly systematized, it would shortly put a value on membership not now felt and, in the end, point the way to a touring department which might include within itself all the benefits that make membership in the Touring Club of France so essential to European motor travel.

Racing Board.—The function and work of the racing board have

been so prominent a part of the history of the Association as to need no comment here. The subject of racing and racing rules can safely be left with the racing board.

The Press.—Absolute impartiality between representatives of the daily or the trade press must be the rule, and any infraction of it should be noted and sharply reprimanded.

Such are some of the considerations which seem to deserve mention at the outset of the present administration. They are put forward, not as pledges, but suggestions. Ready sympathy with and quick response to the official actions of the executive and other committees and boards are essential to efficient work.

I bespeak of you all that cooperation in labor from which alone can come that for which we all give our time and our thought—the greatest good to the greatest number of road users, be they yet motorists or not.

NEW STATE SECRETARY IS ELECTED.

At a meeting of the board of directors of the New York State Automobile Association, held in the clubhouse of the Automobile Club of America, Saturday, January 19, C. D. Hawkes, of Albany, was elected secretary in place of F. H. Elliott, of Syracuse, who resigned to become secretary of the American Automobile Association. O. A. Quayle, the president, announced the appointment of Robert Lee Morrell, of New York, as chairman of the Good Roads Committee, who is authorized to appoint the members of his committee. A legislative committee of twenty-three was also named.

STATUS AND PROSPECTS OF THE INDUSTRY.

By ELLIOT C. LEE,

PRESIDENT MASSACHUSETTS STATE AUTOMOBILE ASSOCIATION.

It can be all summed up in the one word "amazing."

At the time of the New York Show in January, 1906, it was obvious that there was not only a vast increase in the public interest in automobiles, but also everyone could see that the public had, at least for the most part, clearly defined ideas as to the requisites of a satisfactory car. It is not enough to-day that a car should go for an all-day trip without giving trouble on the road, but it must also go quietly; must go up all reasonable hills on the high gear; the control must be simple and quick-acting; the capacity for passengers and baggage must be large, and the car, while amply strong, must not be too heavy. At the Show last year one could see that the makers had endeavored to meet all these requirements, and had, besides, made ample provision, by limousine, landaulet, and other covered or partly-covered bodies, for those who wished to use their cars without being exposed to the weather.

All this could be seen at the Show; but the following season, from March till December, really showed what the automobile industry had become. The increase in the number of cars, especially in the number of large cars, was beyond belief, almost. On Sundays and holidays the main roads in and about Boston were so crowded that it was like a procession or a parade, and not for a few hours only, but all day long. On week days the cars were not quite so numerous, but there were plenty to be seen coming and going on all the roads, and as the season went on the number seemed to increase, steadily and rapidly, until during October, and well into November, if one had been out on the roads for six or eight hours, it seemed as if one had not seen any other kind of traffic at all.

For the ensuing year it is my belief that the growth will be more rapid than ever before. Manufacturers have increased their plants, and the people have now learned that cars are made of a power and endurance to carry their passengers wherever they want to go and for as many hours as they wish to ride—and this will cause a great addition to the number of users, since many have hitherto refrained from buying cars for fear of constant breakdowns, etc. In fact, as far as I can see, the only limitation on the use of automobiles during the next ten years will be the inability of the makers to supply the cars. Even if five million cars are built during that time there will still be in this country some seventy-five million people who are not yet supplied; and other countries will want some, too.

Hotchkiss Administration Should Bring Results. There should be a powerful national organization of automobile users. The American Automobile Association has only partially met the situation. It has promised much, accomplished some things, and left a great deal undone. That which has remained neglected is a fertile field. Every organization must have an energetic leader about whom its members can rally, assist in what he outlines, and enlist others to aid in the work for the general good. It is the busy man who has forced upon him additional duties, for all know that he will do whatever task he assumes. William H. Hotchkiss, the incoming president of the A. A. A., is a man whose time is subject to heavy demands, and reluctantly he consented to take the leadership, and he only agreed because he is aware that automobiling's future requires some immediate attention—to-day and not to-morrow. His inaugural, printed on another page, is recommended to the earnest reading of all automobilists, and if they are not members of the national body the arguments of Mr. Hotchkiss would appear sufficient reason to cause them to make application for such membership at once.

The Crime of False Registration Tags. No more effective way of preventing the reprehensible use of fake registration numbers can be established than that of compelling a visitor from another State to carry a national touring number which shall be issued to him only after he has been properly registered in his home State. The protection of owners who are observing the law requires that these highwaymen of

automobiling be apprehended in a summary manner and be given a punishment of a severe nature and one that will serve as a warning to others who are tempted to disguise their identity with fake numbers. It would be a most convenient arrangement for the registration sign to have on one side the driver's home number and on the other side his national designation. As it is, in those States which recognize the licenses of other States there are automobiles which have never been driven a mile in the States from which their owners pretend to come. This abuse has been an argument frequently employed by autophobes, and it is an evil which should have general attention before the new army of owners takes to the roads in the spring; for though automobiling is now a year-round pastime, the majority of owners prefer a winter season of inactivity. That the practice represents a most facile method of deception as well as one that is most difficult to detect, must be evident on but a moment's consideration of its possibilities. The difficulty of obtaining evidence sufficient to apprehend a suspect is such that the autoist who wishes to avoid payment of the taxes in those States that recognize alien licenses or registration tags has but to purchase one of the latter to be safe from this draft on his pocketbook as well as the more serious certainty of being apprehended through a genuine registration tag in case of accident.

Setting a High Standard for Future Shows.

From whatever point of view it may be considered, the seventh annual show of the Association of Licensed Automobile Manufacturers must be put down as the most successful event of its kind that has ever been held in this country. Whether regarded from a purely esthetic standpoint, or its reverse, the absolute commercial view, including as it does that far from unimportant consideration of matters financial, the show must be conceded to represent an event that will go down into history as having marked a hitherto unapproachable achievement, as well as setting a standard for future events, that will call for strenuous endeavors and no little outlay if it is to be equaled.

Those who had an opportunity of seeing for themselves the magnificent setting that was prepared for the automobile, as well as the beauty and mechanical soundness of the cars that occupied every available foot of space on the main floor and elevated platform of the Garden, need no statistics to impress upon their minds the vastness of the showing nor the elaborate scale on which things were done, while to those who were not so fortunate they must fail to convey anything but a hazy idea. However, a few random figures may not be amiss in that they serve to give an inkling of the extent of the industry that was represented by the gala showing. For instance, 45 exhibitors displayed 230 cars of all types, beside which there were put on view eight of the racing cars that took part in last year's Vanderbilt cup race.

These ranged in price from \$400 to \$12,500, probably averaging something like \$2,000 each for the whole, so that this part of the show alone was valued at close to half a million dollars in round numbers. Add to this the vast assortment of wares, many of them of an expensive nature, shown by the 204 exhibitors of accessories who occupied every square inch of floor room that could not be utilized for showing cars, and the value of the whole approaches a figure that far outshadows anything of the kind ever attempted in this or any other line of endeavor. If this were not enough, the mere fact that the association, under the auspices of which the show was held, felt justified in spending such a sum of money to ornament the building for one week is sufficient to indicate the truly elaborate scale on which the affair was managed. Concerning the show's status as an annual fixture of the metropolitan winter season, the announcement that the city's most prominent hostelrys were all full to overflowing is ample evidence of the strength of its attraction. This, taken in connection with the statement that the last Horse Show did not fill the hotels, is a stronger indication than ever of its potency.

NO ACCESSORIES SHOW NEXT FALL.

Next to the business of electing a set of officers for the ensuing year the chief matter of moment before the Motor and Accessories Manufacturers, Inc., at its annual meeting held during show week was that of passing on the question of holding an exclusive accessory show next fall. After some discussion it was voted down. The following were elected officers

for the coming year: President, H. S. White, Shelby Steel Tube Company; first vice-president, H. E. Raymond, the B. F. Goodrich Company; second vice-president, William H. Crosby, W. H. Crosby Company; third vice-president, E. W. Beach, Manufacturers' Foundry Company; treasurer, W. S. Gorton, Standard Welding Company; secretary, P. S. Steenstrup, Hyatt Roller Bearing Company. The following were elected directors for the same period: D. J. Post, the Veeder Manufacturing Company; J. W. Gilson, the Hartford Rubber Works Company; C. E. Whitney, the Whitney Manufacturing Company; H. T. Dunn, the Fisk Rubber Company; F. E. Castle, Gray & Davis; C. T. Byrne, Byrne, Kingston & Co.; L. M. Wainwright, Diamond Chain & Manufacturing Company. The meeting was held at the Hotel Astor, and there were about ninety members present, either in person or represented by proxies.

PETER S. STEENSTRUP,
Newly elected secretary of the Motor and Accessories Manufacturers, Inc., who conducted the Fifth Hyatt Feast at the Waldorf-Astoria so successfully during show week.

In the course of his address, the president gave a résumé of the year's work, stating that the association now has a membership of 173. The treasurer's report showed the association to be in sound financial condition, while the advertising committee read a detailed report of its work which was received with great interest by the members. Both the president and the treasurer were tendered a rising vote of thanks for their efforts during the past year.

LEGISLATORS ARE BUSY IN ALBANY.

Drastic automobile laws are threatening in Albany. If the bill introduced in the Assembly on January 9 should become law not only would the maximum speed limit be reduced from twenty to fifteen miles, but machines would have to be geared so as not to be able to produce any more than the lesser speed. Three other bills affecting automobiles have been presented to the legislature and more are expected shortly. Assemblyman Hamn's bill gives town boards the right to limit speed outside villages, and would, if passed, bring in a fifteen miles limit in many districts where twenty miles are now permitted. Assemblyman Cuvillier provides in his bill an annual license fee of \$25 for chauffeurs, an examination as to qualifications, a twenty-one-year age limit and ability to read and write English. Assemblyman Stanley has an elaborate measure providing for a State Motor Vehicle Commission, to have entire control of automobiles. Chauffeurs must be at least eighteen years old and a "reasonable and proper rate of speed" must be observed. The Albany Automobile Club favors asking Congress to provide for uniform interstate licenses. An annual tax will not be objected to if the proceeds are applied to the improvement of highways and oiling of country roads. Two later bills provide for insurance against accidents by automobiles, and amend the insurance law by including automobiles in the list of insurable property.

AERONAUTS WILL HAVE BUSY YEAR.

PARIS, Jan. 15.—The year 1907 promises to be one of considerable activity in the French aeronautic world. Comte Henry de La Vaulx has already made two or three successful trial trips in his new steerable balloon, and will very shortly remove to his new balloon garage at Saint Cyr. Walter Wellman, of Polar fame, has installed himself in the vast Galerie des Machines, close by the Eiffel Tower, where he is fitting out his balloon equipment previous to shipment to Spitzburg. The balloon has a total length of 177 feet, and is driven by a 90-horsepower motor. At the end of the month the Aero Clubs of France and Spain will meet at Bordeaux to commemorate the first crossing of the Pyrenees by the late J. F. Duro. Early in the spring the new balloon sheds and inflating station of the Aero Club of France, located at Saint Cloud, near Paris, will be officially opened, and a few weeks later the clubrooms will be removed to a new building in the center of Paris.

Heavier than air enthusiasts, at present busy in their workshops, will come out with their new machines with the first signs of spring. Santos-Dumont is looked upon as a certain winner of the 50,000 francs' Grand Prix, but will have as competitors Captain Ferber, Bleriot, Tatin, Société Antoinette and Comte de La Vaulx.

The new military steerable balloon *Patrie* is awaiting less wintry weather to allow it to make its long journey from Paris to Verdun, its fighting port on the German frontier. Later in the year the *République* and the *Démocratie*, both designed by the engineer Julliot, will join the fighting ranks. The *Lebaudy* will remain at Chalois-Mendon for the training of military officers.

Coming competitions include a long-distance test in May, Le Figaro race in June, the Grand Prix of the Aero Club of France in September, and the Gordon Bennett contest in October, at which France will have a full team. The *Ville de Paris*, M. Deutsch de la Meurthe's new steerable, will attempt to win the \$4,000 cup for the first complete tour around Paris.

A. L. A. M. PRESIDENT ON BRITISH SHOW.

Charles Clifton, president of the Association of Licensed Automobile Manufacturers, has just returned from a trip through Europe. While in London he attended the big Olympia automobile exhibit, and gives it as his opinion that for show methods and artistic treatment the American exhibit is far superior. In respect to the cars, however, Mr. Clifton spoke in high terms of the progressive manner of the English manufacturer, who, like the American maker, seems to have found the keystone of the industry in using materials of a higher quality, with better constructing methods than hitherto, and thus building cars of permanency and reliability.

"The predominant feature in the English automobile industry," he added, "is the pronounced popularity of the six-cylinder car and the number of different makes that are being turned out. It has surely taken root among English motorists more firmly than anywhere else."

MR. VANDERBILT'S INTEREST IN PARKWAY.

A recent cablegram from W. K. Vanderbilt, Jr., president of the Long Island Motor Parkway, Inc., from Paris, sending a substantial subscription, indicates that Mr. Vanderbilt has not ceased to make the Parkway his first care. Mr. Vanderbilt is being kept fully informed as to the progress of affairs, particularly as to the procurement of rights of way. The recent action of the Board of Trade in Riverhead in voting to subscribe to about \$25,000 worth of stock and bonds and its guarantee to secure at least twelve miles of right-of-way and turn the same over to A. R. Pardington, the second vice-president, makes apparent the firm belief of that organization in the benefits to accrue to the town as a direct result of the construction of the Parkway.

GREAT BRITAIN AND THE TOURIST TROPHY

LONDON, Jan. 14.—True to its declared policy of last year, the Automobile Club of Great Britain and Ireland will not lend its support to any international event for racing cars, but will devote all its energies to the improvement of the Tourist Trophy Race. This time the race will be held at the end of May and probably on the same Isle of Man course as before. The rules governing the contest are materially the same as in the previous races, but this time the fuel will be a special brand of gasoline supplied by the club, and allowance one gallon for each 25 miles traversed. Six circuits of the 40-mile course will be made, and doubtless an average of nearly 45 miles an hour may be expected from the winner.

Since the issue of the rules for this race, however, a suggestion advanced by the Society of Motor Manufacturers and Traders has been agreed to by the club, and to-day there are issued rules governing the International Heavy Touring Car Race. This is purposed to be a race for the development of ideal touring cars, such as are usually fitted with covered bodies and of the horsepower required by the ordinary user, as opposed to the racing car. The limitation of power and speed is effected by fixing a definite fuel allowance of one gallon of gasoline for each 16 miles of the course. To be held this year on the Isle of Man in September, the race will be in distance between 250 and 400 miles, and the system of controls will possibly be reintroduced. A total load of 2,240 pounds, inclusive of driver and mechanic, must be carried by the chassis, and while no weight limits are imposed for the chassis, definite standards are set up for size of the track, wheelbase and body. To prevent undue raising of the gears, that Tourist Trophy rule is incorporated which requires a half mile to be covered at a

rate of not more than 12 miles an hour without slipping the clutch. The entry fee is fixed at \$150, and the list will remain open until May 1.

Formation of the Brooklands Automobile Racing Club

has already been chronicled, and great efforts are being made to enable the official opening of the club's track at Weybridge, to take place in May. For the first meeting, provisionally dated May 18, some big prizes are announced, including the Montague Cup of \$10,500; the Gotlieb Daimler Memorial Plate of \$3,250, and the Marcel Renault Memorial Plate of \$2,750, the total of the day's list reaching \$23,000. Plates are offered at first, but later it is intended to run sweepstakes and handicaps when the track becomes more familiar. To the fore, as ever, S. F. Edge has booked the track for the first available day with the determination to set up on a 60-horsepower Napier a new world's 24-hour record, a speed average of 60 miles an hour being reckoned on. Not to be outdone, Charles Jarrot will attempt to lower Edge's record the following day with a 60-horsepower De Dietrich. The battle of the six vs. four cylinders will thus be waged by the foremost advocates of either system, and possibly a race between them will be arranged.

The news just to hand of the proposed European tour of American cars this summer attracts much attention, but it is to be regretted that out of the 4,000 miles total, but 250 miles is allotted for the British share of the tour, this consisting of a "hustle" straight across country to Liverpool. Surely it might be arranged to map out another few hundred miles by embracing Wales and the West of England, and possibly an interesting trip round the Lake District.

FRANCE OFFICIALLY ANNOUNCES THE GRAND PRIX

PARIS, Jan. 15.—The Automobile Club of France is resolved that in the matter of road racing it shall remain at the head of the nations of the world. Its Grand Prix last year—the successor of the Gordon Bennett—was planned to make it the most wonderful road race ever held. This year, on a date to be fixed late in June or early in July, another Grand Prix will be held differing from the last in that the fuel supply will be limited to 6.6 gallons per 62.1 miles. With such a liberal supply of gasoline monsters of 120 and 130 horsepower can be built capable of the highest speeds. Now, even in France, only a few firms have the necessary experience and capital for building high flyers, and there was a danger of the performances of the select few being eclipsed by the big entries obtained in the German Emperor's race and the Tourist Trophy of the British club. Both these are speed contests, the one with a limited cylinder capacity, the other with a maximum fuel consumption, notwithstanding the "Tourist" title of the British event and the tourist mention in the German regulations.

It is probably this which has decided the sporting committee of the A. C. F. to hold Grand Prix No. 2 on the day following Grand Prix No. 1 and over the same course. The second day's race will be for machines with a gasoline supply limited to 3.3 gallons per 62.1 miles. There will be no other restrictions of any kind. Although detailed regulations are not yet published, it is probable that the second race will be on the same lines as that of the first day, with the total distance reduced to 320 miles. There will be no controls or neutralizations; the driver and mechanic will fill tanks, change tires and do all work; a single tire and gasoline station will be placed on the circuit; dismountable rims will be allowed.

With this fuel allowance the machines are likely to average between 40 and 50 horsepower and to develop a speed of 45 or 50 miles an hour. Every manufacturer of importance builds a machine of this type; to fit it for the race would only entail slight modifications and little expense. A big entry is consequently expected, and in view of the success of the Tourist Trophy and the German Emperor's race this expectation is likely to be fulfilled.

Although enthusiastic over the new race, French automobilists do not hesitate to criticise. They ask that the 3.3 gallon machines should run the first day, the original Grand Prix being reserved for the second. Twenty or thirty heavy racers rushing round the course at mile-a-minute speeds will utterly spoil the road surface and make the task of the smaller machines unnecessarily difficult. A big entry is likely to be obtained for Grand Prix No. 2—from 60 to 100 cars are looked upon as probable starters—and if special precautions are not taken accidents will ensue.

Grand Prix No. 2, distance 320 miles, fuel allowance 3.3 gallons per 62.1 miles, is open to teams of three from any factory at an entrance fee of \$700 per car. Entries close February 7, but are received later on payment of an increased fee.

Grand Prix No. 1, distance 500 miles, fuel allowance 6.6 gallons per 62.1 miles, is open to teams of three from any factory at an entrance fee of \$1,000. Entries close on same date. Six machines have already been officially entered—three Bayard-Clément to be driven by Albert Clément, Garcet and Gauderman, three Darracqs with Wagner, Hanriot and Demogeot as pilots. Two Civelli de Bosch machines are also announced as certain starters in this event.

NEW HAVEN'S AUTOMOBILE ACTIVITIES.

NEW HAVEN, CONN., Jan. 21.—The automobile industry has reached New Haven. The University Automobile Company, of this city, C. S. Johnson, president, is now building both runabouts and a 30-35-horsepower touring car. The new machines will be known as the Continental, and the first output will be ready for the market in about two weeks. The touring car will weigh about 2,500 pounds and will embody several novel improvements, among which will be a self-starting device. This company will also carry the agency this year for the Wayne car.

The F. E. Bowers Company has been incorporated and has started the erection of a plant in this city. The new company will for the present confine itself to putting out a new carbureter, which it controls, and is said to give great promise. The new carbureter can be attached to any type of motor. The company will also deal in all automobile accessories. The corporation is capitalized at \$10,000 and will begin business at once. The incorporators are Fredsom E. Bowers, Clarence G. Spalding, Harold P. Warren, and Edward B. Spalding, all of this city.

THE AUTO PROVIDES FINE WINTER FUN.

Detroit has had very little snow this winter, but January 12 brought good sledding and fun for Michigan boys. Young Ford, the twelve-year-old son of Henry Ford, the automobile

EDSEL FORD AND HIS FRIENDS HAVING FUN.

manufacturer, has a runabout out of which he gets much enjoyment driving his mother on her shopping and calling tours and between times giving his less fortunate playmates a ride. With the first snowfall Master Edsel found a new use for the automobile and a way to entertain several friends at once. The accompanying picture illustrates a sight that is familiar to all drivers on Detroit's Grand Boulevard, but it cannot show the speed with which little Ford in his speedy runabout whipped the sleds of the other boys round corners, rolling them over in the soft snow and giving them a touch of high life generally.

THOMAS NON-STOP CAR OFF TO CHICAGO.

With 467 hours and 37 minutes, and a total mileage of something like 2,800 already to its credit, the Thomas car in charge of Ernest Kelly, of Philadelphia, that has been running steadily ever since January 2, when it was started in Harrisburg, Pa., left New York for Chicago Monday afternoon, January 21. It was originally intended to ship the car by express, with observers accompanying it to see that the motor was kept going, but this was abandoned and the trip by road undertaken despite the advice of autoists familiar with the route. The car started on its journey westward from Harry S. Houpt's new Thomas salesrooms, Broadway and Sixty-third street.

NEW CORBINS ENJOYING THE YEAR'S FIRST SNOWSTORM.

FIRST SELDEN CAR READY THIS SUMMER.

The Selden Motor Vehicle Company, of Rochester, N. Y., recently organized with a capital of \$500,000, expects to have its first new car on the market by the middle of the coming Summer. The appearance of this car will be awaited with much interest, particularly owing to the fact that E. T. Birdsall, one of the pioneer mechanical engineers of the automobile industry, is the chief engineer of the Selden company and the designer of its car. Mr. Birdsall was a technical adviser of the Vanderbilt Cup Commission for several years, is secretary of the Society of Automobile Engineers and has been a prominent official in many of the important race meets and touring contests held in this country. Frank D. Russell, who has been identified with the Rochester Car Wheel Works for the past fifteen years, will have personal charge of the manufacturing end of the Selden company, the plant of which is being located at East Rochester, where building operations are already under way. The plant will cover over eight acres of ground.

The Selden directors for the first year are: George B. Selden, George G. Foster, Frank D. Russell, Gilbert E. Mosher, R. H. Salmons and J. M. Walmsley, of Rochester, and Louis A. Fischer, A. Snyder and A. G. Bartholomew, of Buffalo. With Mr. Selden as president, the other officers are as follows: First vice-president, Louis A. Fischer; second vice-president, J. M. Walmsley; treasurer, Gilbert E. Mosher, and secretary, R. H. Salmons.

EDWARD RUSSELL THOMAS IN THOMAS "FORTY" RUNABOUT.

Considerable confusion results generally through the fact that the New York banker and the Buffalo automobile manufacturer bear the same name. The two men are not related. Mr. Thomas' sister occupies the other seat in the runabout alongside him.

PRACTICAL TESTS OF DIFFERENT FUELS.

With a view to determining more definitely just what can be done with alcohol, kerosene, benzine, naphtha, etc., for automobile use, the Maxwell-Briscoe Motor Company have just undertaken a series of tests on the road and in the laboratory. Probably picric acid will be experimented with also, in order to determine what percentages of this high explosive are practical in

MAXWELL CAR FITTED FOR SPECIAL FUEL TESTS.

connection with the fuels ordinarily used, though its employment is not at all advisable under any circumstances, even though greater speed and power are obtainable. Though "naphtha" and "benzine" are included in the list of fuels, which, it is stated, will be tested, it may be as well to add here that these are but other names for the same substance which is more generally known as "gasoline," so that the results of a formal test of their power-producing qualities would be apt to be misleading unless this were taken into consideration. Originally these names were employed to designate the varying specific gravities of the different products of distillation, but they have long since become nothing more than trade names for the same thing.

The first road test will take place this week, when three Maxwell runabouts will be driven from New York to Boston, using different fuels. One motor will be operated with gasoline, another with kerosene, and still another with denatured alcohol. Observers will be appointed by the New York Motor Club to make official reports on mileage and the quantity and cost of each fuel used. Stock cars will be used, since the experiments at the Tarrytown factory have demonstrated that a Maxwell motor will run on kerosene, alcohol or gasoline.

The chief object of the tests is to demonstrate that fuels of varying specific gravities, or density, can be used to advantage in the same carbureter. Aside from gasoline, the chief of these are alcohol and kerosene, the latter being far heavier and less volatile, which accounts for the difficulty in starting the motor on it from all cold. Both the first cost and consumption of alcohol are far greater in the present type of motor than when using gasoline, and not as much power is developed, owing to the fact that neither the compression nor the stroke are such as to utilize the expansive force of alcohol to the best advantage. There is not so much difference in the case of kerosene, and the average motor will run on it almost as well as with gasoline once warm enough to vaporize the fuel. The photograph shows the special tank fitted to the dash of a Maxwell two-cylinder car for the purpose of the tests. The data gathered will be made public later. H. A. Grant, M.E., is conducting the experiments.

Two new garages are to be built on Long Island for the coming season. One will be located at Glen Cove, the other at Bay Shore. Both will make a specialty of catering to the rapidly increasing Long Island tourists' wants.

A FRENCHMAN ON AMERICAN INVASION.

Commenting on the proposed invasion of Europe by American automobiles, Paul Meyan, a prominent French automobilist, says: "The American industry has not yet settled on definite lines; efforts are dispersed and groping—luckily for us. But as soon as the American producer has reached a higher stage he will confine himself to the production of a single type of car and turn them out in such quantities that local needs will be more than supplied. Half of the machines will be sold at home, the other half will be sent to conquer foreign markets, where they will be sold at cost price. We shall not be able to stand up before such competition; our flourishing export trade will be killed by the American series. We have only one means of protection—a customs duty. With a thirty-million-dollar export trade we are told that we have no need of protection. That is a theory; it has not yet been proved that it is a good one."

Advocates of the protectionist theory will find much satisfaction in the arguments advanced by M. Meyan. The pros and cons of the question are worth a careful investigation.

NEW SCHEBLER PLANT AT INDIANAPOLIS.

The new Schebler carbureter plant at Indianapolis, Ind., which will be ready for occupancy in about two weeks, is built of reinforced concrete and shale brick. This plant covers an entire block, and is located at Shelby and Sanders streets and Barth avenue. Its output will be 10,000 carbureters a month, and when running full force will employ nearly 500 men. Two years and a half ago, when the Schebler was first brought out, two men were employed to make the carbureters. The wonderful increase in the automobile industry is shown when a part maker in two years' time increases his facilities from an output of 400 carbureters a year to 100,000 carbureters a year. Mr. Wheeler states that the business during 1907 will run to about a million and a half dollars, according to orders now booked.

The foundry proper has the largest concrete arches above ground in the world, the span being 65 feet, without a post or support. The length of this room is 135 feet. The roofs and floors are all reinforced concrete, the foundry having a circular roof, which is a new idea in concrete construction. The

NEW HOME OF THE SCHEBLER CARBURETER AT INDIANAPOLIS.

stacks for the powerhouse are also of reinforced concrete. All modern conveniences for employes are furnished, even to lockers and showerbaths for the men. The power is generated by suction gas producers, which give 125 horsepower at a cost of only half a ton of coal a day. The cost of this plant complete, with equipment and machinery, approximates a quarter of a million dollars.

IN AND ABOUT THE GARAGES.

Modern and Finely Equipped Garage for Schenectady.

Close Brothers, of Schenectady, N. Y., are making preparations to erect a large garage in that city at a cost of about \$40,000. The location chosen is on Smith street, and the building will be of fireproof brick construction, two stories high with a basement. It will have a frontage of 31 feet on Smith street, will run back along the alley a distance of 180 feet, and will have facilities for storing 200 automobiles. There will be a glass-front vestibule, back of which will be the offices, and back of the offices will be situated a handsomely furnished parlor for ladies. On the east side there will be a passageway 12 feet wide, which will be used as an entranceway for cars. In the rear modern facilities for washing cars will be installed, and the building will be equipped with elevators running to the second floor and to the basement. Work on the building will be started at once.

New Chicago Garage Opened New Year's Day.

The Model Garage Company is the newest arrival in the Chicago field, its fireproof structure at 645-647 East Forty-seventh street, near Grand Boulevard, having been opened on New Year's Day. The officers of the company are: President, J. N. Williams; vice-president, C. Tindolph; secretary and treasurer, C. W. Williams. The building is of iron and concrete construction, 135 feet by 50 feet. Elegantly furnished reception rooms have been fitted up for the use of lady patrons on the first floor, and on the second floor is located a reading and lounging room for chauffeurs. The repair department is fitted with the latest and most approved machinery.

Big Automobile Shed for Garfield Park, Chicago.

In connection with some other extensive improvements which include the erection of what it is reported will be the largest greenhouse in the world, at Garfield Park, the city of Chicago will erect directly across the driveway from it an immense automobile shed. Garfield Park is the site of these improvements, which will cost, exclusive of the green house plants, in the neighborhood of \$250,000. The gardens will be located near Madison street, and will be connected by a pathway with the music court.

New Management for Prominent New York Garage.

The premises formerly occupied by the Central Park Automobile Storage Company, Central Park West and 110th street, have been opened under new management by C. Herbert Covell, president of the Covell & Crosby Motor Company, and agent for the American Car. Extensive improvements are under way, and when completed will make this one of the finest uptown automobile garages.

Plans for the New Pierce Garage in New York City.

Plans have been filed for a four-story garage to be built for the Kipps Bay Realty Company, at 233-237 West Fifty-fourth street. The building is to have a frontage of 60 feet and a depth of 90 feet, the façade being of brick trimmed with limestone and terra cotta and ornamented with bays. It is to cost \$100,000, and upon completion will be occupied by the Harrolds Motor Company, New York agents for the Pierce.

A WELL-KNOWN MAKE OF MOTORS. ✓

Brennan motors scarcely need any introduction, whether to the marine or automobile interests—during the number of years that they have been on the market they have become so well and favorably known that anything on this point would be superfluous. For 1907 the makers of the Brennan motors are specializing to an even greater extent on the four-cylinder vertical type, though the horizontal, double-opposed and four-cylinder opposed types with which their name has always been connected

BRENNAN MOTOR, SHOWING WORKING PARTS IN BASE.

are continued as usual, together with the various types of sliding and planetary change-speed gears with which they are sold, making a complete power plant of almost any capacity required. The two-cylinder horizontal motors are made in seven sizes ranging from 6 to 30 horsepower, the four-cylinder horizontal in three sizes, 28, 32 and 40 horsepower, and the four-cylinder vertical type in four sizes, rated at 12, 18, 32, and 45 to 50 horsepower.

With the exception of the varying dimensions all are the same, a standard form of construction having been adhered to throughout each series of motors. Thus the cylinders are separately cast with integral waterjackets, the inlet valves are centered in the heads and operated by push rods and rocker arms, the exhaust valves being at the side. The crankshaft is made from a solid billet of nickel steel and is supported on five ample-sized bearings. The latter are made from a special bronze possessing many of the advantages of babbitt without its disadvantages. All bearings and working parts are made fast to the upper or main section of the crankcase, the latter being divided at an angle of 40 degrees, thus giving free access to every part of the motor from one side of the case, this being well illustrated by the accompanying photograph of the standard type of Brennan motor. The timer is mounted on a vertical shaft, bevel-gear-driven from the end of the camshaft, and is well protected by an effective casing. The water circulating pump is gear driven and is of the gear type. The dimensions of the various sizes are 3 5-8 by 4 inches, 12 horsepower; 4 by 4 inches, 18 horsepower; 5 by 5 inches, 32 horsepower. and 5 1-2 by 6 inches, 45 to 50 horsepower, the normal speed being 800 r.p.m., except in the case of the first named, in which it is 900 r.p.m., though the speed range is from 150 to 1,800 r.p.m. in the case of the smallest, 1,500 in the two intermediate sizes, and 1,200 r.p.m. for the largest.

WHITE 'BUS THAT WORKED HARD DURING SHOW WEEK

TWO-PASSENGER AUTOCYCLE RUNABOUT.

A glance at the accompanying illustration will explain more clearly the principle of the Autocycle two-passenger bicycle-runabout than any word description. This machine has been designed to embody in one vehicle the speed, comfort, and

VANDEGRIFT TWO-PASSENGER AUTOCYCLE.

utility of the automobile with the simplicity, lightness, and cheapness of the bicycle. The body of the Autocycle is carried upon a front steering and rear driving wheel placed tandem in the center line of the vehicle. Upon either side, connected by an axle, are smaller balance wheels which maintain the equilibrium of the vehicle, but ordinarily take little or no weight. By the use of a specially designed link check spring device these wheels remain at all times in contact with the roadway; they turn in unison with the front wheel, each at its proper angle in rounding a curve.

Power is obtained from a two-cylinder 3 1/4x3-inch air-cooled motor, developing 6 horsepower at 1,800 revolutions. Drive is direct by a belt from a pulley upon the main shaft of engine to a pulley upon the rear wheel. The motor equipment includes float feed carbureter, four dry-cell batteries, two coils, oil feed, and three-gallon gasoline tank containing fuel for 120 miles. The rear driving wheel revolves with an axle carrying a three-quarter elliptic spring upon either side, supporting the extended arms of the chassis. Ball bearings are fitted in the revolving axle, and on the side opposite to the belt pulled is an expansion brake.

Steering is through an inclined column with the ordinary type of hand wheel. The steering head turns upon thrust ball bearings. Throttle and spark control is by means of levers immediately under the steering wheel.

The body of the Autocycle is of wood, the seat and back upholstered in machine-buffed leather. There is seating accommodation for two people. The total weight of the machine is 380 pounds, and its catalogue price \$400. It is manufactured by the Vaudegrift Automobile Company, Thirteenth and Cumberland streets, Philadelphia.

PRIVATE AUTO ROAD TO REACH TUXEDO.

A private automobile highway 45 miles long is to be constructed from the Forty-second street ferry, New York, through the Jersey meadows and Northern New Jersey to Tuxedo, N. Y. It is planned to have the course consist of two tracks thirty-five feet each in width, divided by a thirty-foot road raised to a height of four feet, on which will be built a double track railroad. At each cross road there will be a toll gate and station constructed so as to allow automobiles to pass under the station, thereby making an absolutely open course for the entire forty-five miles. The Motor Car Roadway Company has been organized for the purpose of constructing the highway with a capital

of \$10,000,000, of which \$4,000,000 is to be six per cent. preferred stock. Work on the road is to begin early in the spring and to be completed in two years.

RUNABOUT DESIGNED FOR POPULAR FAVOR.

In designing the Brush runabout no attempt has been made to produce a spectacular car or to turn out an imitation of a high-priced machine. The horse and buggy is an expensive nuisance; a runabout specially designed to meet the needs of those who have heretofore been unable to buy—or if able to buy unwilling to support—a car of the conventional type, is an economical convenience.

The Brush runabout has been built to sell at \$500. Low running expenses have been borne in mind, and it is estimated that the total cost for 5,000 miles, including tires and repairs, should not be more than \$75 or \$100.

A 6-horsepower single-cylinder vertical engine supplies the motive power. It is carried forward under a bonnet, thus making it fully accessible, and is water cooled. With this horsepower more than the legal speed can be maintained, while fuel and oil cost is reduced to a minimum.

As this type of automobile generally gets into the hands of persons of little experience, special care has been taken to give it an absolutely safe fuel system. The tank is the lowest part; the fuel is taken out at the top, and only while the motor is running. There is no float or float valve, no pump plunger or gland, no pressure in the tank, and all piping is above the highest gasoline level. The change-speed mechanism provides eight set speeds, direct drive on the high; gears may be shifted without releasing the motor, and there is no noise or shock in changing. The change-speed mechanism and brakes are commanded by two foot pedals, giving remarkably easy control. The steering gear is irreversible; it is slow and powerful for straight ahead, but accelerates as the steering wheel turns, so that three-quarters of a turn puts it hard over.

Little items of convenience have been carefully studied. Thus the spark plugs may be instantly inspected without unscrewing or disconnecting the wire. Access to the connecting rod bearings is almost instantaneous. Both valves can be removed in thirty seconds. The sight-feed oiler on the dash is automatic. Sprockets are interchangeable, so that when one side of the tooth is worn they can be reversed.

The Brush runabout is equipped with coil-spring suspension because considerably less than one-half of the weight of spring is required, and because there are fewer joints. With the coil springs is combined a friction-spring retarder or shock absorber, so that the regular equipment of solid tires give very easy riding. Pneumatic tires can, however, be fitted.

This machine is being built by the Brush Runabout Company, having its headquarters in Detroit. Deliveries in quantities will begin April 1 and continue, according to the makers' statement, at the rate of fifteen per day.

DETROIT'S LATEST PRODUCTION—THE BRUSH RUNABOUT.

INTERNATIONAL BALLOON RACE, OCT. 19.

At a meeting of the Aero Club of America held Tuesday afternoon, October 19 was confirmed as the date for the international race at St. Louis, and some of the details were arranged. Nine countries will be represented, and a committee was appointed to name three Americans to defend the cup; its report is to be handed in before February 20. A valuable prize has been offered for an aeroplane through the club by a wealthy American, and the former will draft the conditions under which it is to be competed for.

NEW INTERNATIONAL CONTESTS ARRANGED.

The Paris to Madrid tour, announced with a great beating of drums a few weeks ago, has been abandoned by the A. C. F. Instead will be held a 2,500-mile tour for runabouts of the doctor's type, two or four-cylinder, 12-horsepower, to average 150 miles a day at a speed of 19 miles. Also a commercial vehicle competition for both light and heavy cars, over the same distance. The tour will be held around Paris, penetrating more into the industrial east and north than into the agricultural communities of the south and west.

THE HON. C. S. ROLLS RETURNS TO ENGLAND.

After a three months' visit to the United States and Canada, the Hon. C. S. Rolls returned to England this week by the *Kaiserin Augusta-Victoria*. Interviewed by *THE AUTOMOBILE* correspondent, Mr. Rolls said he did not expect to be back in America until the month of October, probably one week before the balloon race at St. Louis, in which he will form one of the British teams. He will bring with him the *Britannia*, a 77,750 cubic feet balloon, built by Short Brothers, of London, last year, with which he won third place in the first Gordon Bennett race and remained in the air longer than any of his competitors. Mr. Rolls has formed a company in New York under the title of the Rolls-Royce Import Company, to handle his British-built machines. Two six-cylinder models only will be sold in the States; the four-cylinder type which won the Tourist Trophy in the Isle of Man has been sold out, and it has been decided not to continue its construction. In Canada, where Britishers enjoy a preferential tariff, Mr. Rolls believes that good business will be done. In the United States importers have greater difficulties, American machines having enormously improved during the last two years, though in the opinion of the Englishman they are still built too light.

HOW TO CLEAN AN AUTOMOBILE.

There is some excellent advice given by John T. Stanley, manufacturer of "Mobo," and though he naturally talks about his own preparation his advice has a general application. These are the directions which he gives:

As soon as the car comes in from a run play water from a hose all over the varnished surface. Then let the car stand some minutes, so that the water can penetrate and soften the mud spots. Now use the hose again, playing the water on hard, so as to wash off all the heavy mud and grit. Do not use a sponge, as it will spread all the grit particles over the varnished surface and scratch and mar its luster. Dissolve enough Mobo in water to turn the liquid to a bluish color and to a soft and soapy consistency. Apply the solution to all the varnished surfaces of the machine with a clean sponge, giving a little extra rub to the very dirty and badly stained spots. Then rinse off at once with clear water before the solution dries. After this, dry all the varnished parts thoroughly with a clean chamois.

Do not clean the body of the car with the same sponge used for the wheels and gearing, as in cleaning the latter more or less grease collects in the sponge, and when brought in contact with the highly varnished parts of the car has a tendency to give it a cloudy and smeared appearance.

LOCOMOBILE FOLDING AND REVOLVING SEAT IN POSITION

AN INGENIOUS LOCOMOBILE FOLDING SEAT.

Practical tourist requirements have been kept in view by the designer of the two folding seats shown in the accompanying cuts on a Locomobile car. The seats are the revolving type with upholstered seats and backs. They are peculiar in that all parts, even the irons holding them in place, may be quickly removed and stored on the car in a special compartment designed for the purpose. On touring cars, where space is often needed for dress suit cases, etc., this is a most sensible arrangement. These seats are practically as comfortable as Pullman chairs, but if there is any difference it is more than compensated by the great advantage of being able to get rid of them when they are not wanted.

LONG-DISTANCE TRAVEL BY MOTORCYCLE.

Stanley Bowmar's trip from Buffalo, N. Y., to San Francisco, Cal., on a three-horsepower spring frame Merkel motorcycle having come to a successful termination, the intrepid rider will very shortly set out on another long journey, visiting Los Angeles, Pasadena, San Diego, etc. Mr. Bowmar has taken up the Merkel motorcycle agency on the Pacific Coast, where, thanks to the good roads and favorable weather conditions, motorcycling is in high favor. After spending some time in California Mr. Bowmar expects to depart for his home in New Zealand, in which country he will do further traveling by motorcycle.

The Locomobile line for the coming season shows no more vital change than the general use of annular ball-bearings, of the Hess-Bright silent type, practically everywhere except in the motor. This car had plain bearings throughout as recently as last year on some of the models.

LOCOMOBILE SEATS FOLDED INTO COMPARTMENT.

NEWS AND TRADE MISCELLANY.

Philadelphia's original automobile show promoter, H. D. Le Cato, is to get into the game again, having announced a Sportsmen's and Motor Show at the Horticultural Hall, in that city, for March 6-9.

The Cornish-Friedberg Company, of Chicago, is preparing to put on the market a 16-horsepower shaft-driven runabout. This car was especially designed by Mr. Friedberg to meet the growing and popular demand for a car of this type.

The Holland Launch & Engine Company has been organized at Holland, Mich., with a capital stock of \$15,000 for the purpose of making boats and motors. It will occupy the plant formerly used by the Wolverine Company, which has moved to Bridgeport, Conn.

W. W. Campbell, director of Lick Observatory at the University of California, has ordered a Rambler to be used in passing to and from the observatory on Mt. Hamilton. The grades are long and steep, and a more rapid and convenient means of transportation than horses has been for some time desirable.

T. C. Whitcomb, of Cleveland, has formed the Cleveland Auto Livery Company. The new concern will handle the automobile livery business which heretofore has been a branch of Mr. Whitcomb's agency business. Mr. Whitcomb has made a success of the livery business by using good rigs and employing competent drivers.

J. M. Quinby & Co., of Newark, N. J., have completed an extensive addition to their plant, and are installing a complete repair shop for overhauling high-grade cars. This new branch of the business will be under the supervision of Robert Richards. Quinby & Co. will carry in stock at all times a full line of high-grade chassis of the Renault, Fiat, Panhard and Simplex, fully equipped with Quinby aluminum bodies.

Among the Pittsburg companies which were represented at the recent New York show were these: American Automobile Company, Auto Repair Company, D. P. Collins Company, Ft. Pitt Automobile Company, Hiland Automobile Company, Iams Motor Company, E. F. Nevin, Schenley Automobile Company, Standard Automobile Company, Union Automobile Company, Winton Motor Carriage Company and Wilkinsburg Automobile Company.

Tennant Motor, Limited, is the new title for the Northern Motor Car Company, of Chicago, agents for the Peerless and Northern lines. W. G. Tennant has succeeded W. J. Boone as president of the company, and A. G. Brown succeeds K. G. Conway as treasurer. Martin E. Hon remains as secretary, and Clinton Hunter will continue in the position of sales manager. The company will also handle the Mercedes, which Mr. Tennant represented.

To such an extent has the business of the Liberty Automobile Company, Pittsburg agents for the Wayne, grown that larger quarters have become imperative. Work has already begun on an addition to the present quarters at 138-140 Beatty street, East End, which, when completed, will give a frontage of 80 feet and a depth of 110 feet. The new structure, which will be absolutely fireproof, and contain all the features that go to make up a modern sales and storage room, is to be completed March 25.

That outdoor automobile shows are profitable is proven by the statement just

completed of the open-air show and carnival held at the Empire track in New York last May by the New York Automobile Trade Association. The profits permit a dividend to the exhibitors of almost twenty per cent., and checks are now being mailed to the exhibitors by the show committee. There is talk of having another show this spring when the selling season is at its height, but whether Empire track will be the location has not been decided.

The Barndt-Johnston Auto Supply Company, of Columbus, O., is erecting a large addition to its plant on Donaldson street to take care of its rapidly increasing business. The new building will be 50 by 100 feet in dimension and will about double the capacity of the plant. The company was incorporated about a year and three months ago with C. Chris Born, president; W. R. Johnston, vice-president and general superintendent; Louis P. Hoster, treasurer, and Charles F. Barndt, secretary and general manager. The company manufactures all kinds of automobile bodies, tops, glass fronts and other accessories.

A novel and at the same time very practical way of demonstrating the value of the Hotchkiss shock eliminator was inaugurated by Mr. Hotchkiss at his exhibit in the recent Madison Square Garden show. A full-sized cinnamon-colored "Teddy Bear" was placed in a seat suspended above a set of carriage springs fitted with the Hotchkiss shock eliminator. The springs were strongly depressed and suddenly released, but so gentle was the recoil that Mr. Teddy hardly budged in his seat. When the shock eliminator was taken off, and the same process gone through with, Teddy Bear took a long jump skyward.

In the recent Denver-Colorado Springs speed and reliability run the winning car, a 24-horsepower Premier touring car, driven by M. B. Fechter, covered the 80 miles in two hours and twenty-eight minutes, which is an average speed of 32 4-10 miles per hour, eleven minutes better than its nearest competitor. Since the railroad schedule time to the same point is three hours and fifteen minutes, it is noteworthy that the automobile has a big margin to the good. Excepting the run to Littleton, ten miles south of Denver, it is a prairie road to Colorado Springs, through deep arroyos or sharp ravines washed out by the terrific rains. There is a constant rise in the run of 45 miles from Denver to Palmer Lake.

J. B. Herreshoff, the world's greatest speed boat designer, who, though sightless, came down from Bristol, R. I., to get in touch with the Automobile Club of America's show, through the marvelous perspective faculties of his fingers, was accompanied by Mrs. Herreshoff and his son Harold, who acted as his guide. At the Cleveland booth he stopped and passed his facile fingers over the car, following the lines of the fenders, the shape of the seats, and upholstery and the taper bonnet. Standing on the low platform, he remarked that the tires were .36 inches, after feeling their height; but, as he stepped back off the platform, he said: "Oh, no, they are only 34 inches, because your platform is two inches high."

RECENT TRADE REMOVALS.

Wednesday, January 23, the new Philadelphia salesrooms of the Autocar Company, at 249 North Broad street, were formally opened. Over 2,000 invitations were issued.

The Rutland Machine and Auto Company, of Rutland, Vt., has removed from West street to 55-61 Wales street, where they have fine new quarters with every modern improvement, and 10,000 square feet of floor space.

The Boston branch of the Studebaker Automobile Company is now occupying part of the store at 15 Berkeley street, for some years the headquarters in the Hub for the Locomobile. About February 1 the Locomobile branch will be removed to Newbury street, near Massachusetts avenue, and the Studebaker will occupy the Berkeley street store.

The George H. Lowe Company, Boston agents for the Aerocar, will be located at 509 Tremont street, the other end of the store facing at 4 Warren street. The location is a well-known one in the automobile trade, having been occupied by the White Company for a number of years prior to the removal of that company's Boston branch to Newbury street.

NEW AGENCIES ESTABLISHED.

John H. Bawden, Jr., will handle the Rambler line at Freehold, N. J., during the coming season.

Pardee & Canary have secured an agency for the Renault car for Chicago, through E. Lamberjack & Co.

Francis B. Morris, 258 North Broad street, Philadelphia, has secured the local agency for the Aerocar.

The Krueger Manufacturing Company, 56 Biddle street, Milwaukee, has taken the Wisconsin State agency for the Premier.

H. A. Knease & Sons have secured the agency for the Rambler for Iowa City, Ia. They will also open a garage in connection with the business.

The Grout Brothers Automobile Company, of Orange, Mass., has placed an agency in the city of Pittsburg, Pa., in the hands of the Central Auto Company, Ltd., 5489 Central avenue.

Smith & Mabley, Inc., appointed the following agents for their line during the recent Madison Square Garden show: Dudley Riggs, for the State of Connecticut; George C. Miller Carriage Company, for Cincinnati, O.

The Anderson Auto Company, of Greenville, S. C., has secured the agency for the Reo and Rambler. The concern is a new one and has opened a garage and salesroom on West Whitner street under the management of J. C. Stribbling, Jr.

William G. Bell, formerly salesman for the Woods Motor Vehicle Company, has taken over the Chicago Auto Garage Company's property, 3210 North Clark street, and will act as north side agent for R. M. Owen & Company, representing the Reo and Premier in addition to doing a general garage business.

The Holmes-Schmidt Motor Company, of Chicago, has been reorganized, O. P. Schmidt retiring to give his entire attention to the construction of the new Marathon car. C. H. Martin has joined the former firm, which will be known as the Holmes Motor Company and will handle the Welch and the Queen.

Competition in electric vehicles has been further enhanced in Chicago by the opening of an agency for the Baker electrics with headquarters at 1413 Michigan avenue, formerly occupied by the Cassaday-Fairbanks Manufacturing Company. G. R.

Pierce and N. G. Isbell are interested in the agency; J. S. Gorham will act as electrical engineer and sales manager.

The Brazier Automobile Works, of Philadelphia, has established a sub-agency for the Marmon car at Wilmington, Del., with the Motor Car Repair Company. The Spencer-Wilkie Motor Co., which represents the Jackson and Glide cars in the Quaker City, has established a sub-agency in Chester, Pa.

The Standard Brake Company, 101 West Sixty-sixth street, New York, has concluded negotiations with the National Brake & Clutch Company, of Boston, Mass., whereby it has become the sole representative of that company for the United States, covering the use of cork inserts in brakes and clutches for automobiles. Among the twenty-two companies that have adopted cork inserts are such representative manufacturers as Thomas, Rainier, Stevens-Duryea, Knox, Pierce and Nordyke & Marmon. An equitable form of license has been prepared for those companies desiring to manufacture.

PERSONAL TRADE MENTION.

Everett K. Barnes, formerly in the automobile business in Rockford, Ill., has purchased an interest in Pardee & Canary, Chicago.

H. B. Sands has discontinued his active interest in the Plaza Automobile Company, of Brooklyn, and has just joined the selling staff of Smith & Mabley, Inc.

L. M. Cotton, formerly representing the St. Louis Motor Car Company in Boston, has been placed in charge of the Chicago branch of the company, with headquarters at 1223 Michigan avenue.

Robert J. Schmunk, formerly with the White Company's Boston branch, has been appointed assistant manager of the Buck & Price Company, New England distributors for the Rainier car, at 901 Boylston street, Boston.

W. S. Littell, formerly with the experimental department of the Winton Motor Carriage Company, at Cleveland, has gone West and assumed charge of the repair department of the Broadway Automobile Company, at Seattle, Wash.

C. W. Wyckoff, of Wyckoff, Church & Partridge, New York City, is taking a few days' rest at Atlantic City. Mr. Church has gone to Ormond for the races, and Mr. Partridge will take a short respite from business at Lakewood, N. J., in the immediate future.

James Joyce, formerly superintendent of the American Locomotive Automobile Company's plant at Providence, R. I., has just received the appointment as manager of the Albert Frank & Company, with headquarters at the garage, 1886 Broadway, New York City.

O. E. Child has been elected secretary of the Deere-Clark Motor Car Co., Moline, Ill., to succeed C. F. Drury. The company's new directors are C. H. Deere, W. E. Clark, C. H. Pope, C. E. White, A. R. Ebi and A. E. Montgomery. Messrs. Deere and Clark are president and vice-president, respectively.

Thomas Midgley, for the past year president of the Hartford Rubber Works Company, will at a very early date take up, in addition to his other duties, the important position of general consulting engineer to three tire companies—the Hartford Rubber Works, Morgan & Wright and the G & J Tire Company.

NEW TRADE PUBLICATIONS.

"Hawthorne Works" is an illustrated and descriptive booklet published by the Western Electric Company describing their new 110-acre plant at Hawthorne, Ill. Electric power apparatus and switchboards up to and including the largest sizes for street railway service are now a feature of the company's output.

Exceedingly useful hints on the care of solid rubber tires are included in the handsome booklet entitled "Economy in Motor Tires," issued by the Firestone Tire & Rubber Company, Akron, Ohio. These suggestions have been compiled with the personal co-operation of the largest motor tire users in New York and other cities. The subject matter on "Economy in Repair" is also interesting.

Adam Cook's Sons, 313 West street, New York City, the only makers of "Albany Grease," have just issued a new booklet dealing with automobile lubrication. The text is interspersed with drawings showing just how Albany grease is applied in packing compression cups, transmission gears, etc., of interest to everyone who appreciates what an important feature lubrication has become in the economical running of the automobile.

RECENT INCORPORATIONS.

Spartanburg Automobile Company, Columbia, S. C.; capital, \$5,000. Incorporators, F. L. Bryan, Charles Parker and others.

Pullman Automobile Company, Chicago, Ill.; capital \$2,500. Incorporators, Charles O'Brien, H. L. Burnette and J. A. Burt.

Aurora Motor Works, Aurora, Ill.; capital, \$30,000. Incorporators, James Selkirk, William George and Theodore Worcester.

Thomas Spark-Plug Company, New London, Wis.; capital, 5,000. Incorporators, J. F. Thomas, H. J. Bollinski and R. N. Van Doren.

Klink Motor Car Manufacturing Company, Dansville, N. Y.; capital, \$400,000. Directors, F. R. Driesbuch, N. Uhl and E. O. Hoffman, Dansville.

Portland-Rockland Automobile Company, Rockland, Me.; capital stock, \$10,000. Promoters, John A. Lester, Howard A. Sanborn, Percy M. Andrews.

Bond Bros. Co., Portland, Maine; capital, \$10,000. To make and deal in automobiles. Pres., G. A. Hutchins; treasurer and clerk, C. H. Tolman, Portland.

Devac Auto Company, East Orange, N. J.; capital \$500,000. To manufacture motors, automobiles, etc. Incorporators, F. C. Ferguson, Charles O. Geyer and A. W. Candit.

H. Bocker Company, Bronx, N. Y.; capital, \$5,000. To manufacture boats, engines and motors. Incorporators, William F. Wahrenberger, Henry Bocker and Elizabeth Caron.

Oakland Auto Livery Company, Oakland, Cal.; capital stock, \$25,000. Incorporators, J. W. Hoag, C. B. Newman, W. R. C. Jenks, Edwin H. Pendleton and Rodney Wilson, all of Oakland.

Victor Automobile Manufacturing Company, St. Louis, Mo.; capital, \$2,500. Incorporators, Robert Horne, Grace Horne, Julia H. Harrington and Joseph F. Harrington.

Rahler Motor Car Company of Illinois, Chicago, Ill. To manufacture and deal in vehicles; capital, \$20,000. Incorporators, John T. Rahler, Paul N. Lineberger and Edward Q. Corder.

Austin-Hutcheson Company, New York City; capital, \$5,000. To manufacture automobiles and carriages. Incorporators, Howard B. Hutcheson, Louis C. Hutcheson, Carol F. Hutcheson, New York.

Okey Motor Car Company, Columbus, O. To manufacture automobiles and engines; capital, \$25,000. Incorporators, Perry Okey, Campbell Chittenden, F. M. Hoover, H. T. Stewart and H. E. Walton.

NEW FEATURES FOR JONES.

The 1906 model of the Jones speedometer was accepted as a most perfect speed indicator. In the Automobile Club of Great Britain and Ireland's reliability contest it finished with an absolutely clean slate and won the club's gold medal or highest award. The 1907 models are practically the same in construction and design as those of 1906. A new and valuable feature adding largely to the value of the Jones is the addition of a second maximum hand. In using two hands one is placed directly above the other as in a stop-watch. The upper hand is black, the lower red; each move independently of the other. The black hand indicates the exact speed at all times, changing with every change of speed and is permanent at that point, until changed by a touch on the resetting stem which is provided for that purpose. If a car is traveling at 25 miles per hour, for instance, the red hand indicates

JONES SPEEDOMETER FOR 1907.

25 and stops at that point. Now the car reduces speed to 10 miles per hour—the red hand remains at 25—the black returning to 10.

If an officer should signal the automobilist to stop while traveling at say 12 miles per hour, by a simple press on the button, the red hand instantly flashes to the speed at which the car is traveling and remains there—it does not return to zero. Here is proof and proof positive that the speed limit has not been exceeded and Mr. Autoist continues on his way. Heretofore the indicating hand returned to zero when the car was not in motion and arguments were practically always settled in court.

The second or red hand will also prove invaluable to the manufacturer for "try-outs." Cars are frequently sold to enthusiasts on a guarantee that they will "do" a certain speed. By use of this new instrument the red hand will indicate the highest speed and stop at that point. If at any time one should not want to use the red hand, by a simple turn of the resetting stem it is made possible for both hands to move together.

Of course, the instruments retain the odometer register; both trip and distance. The former registers distance to 100 miles; the latter to 10,000 miles; the "trip" is provided with an instantaneous re-setting stem—an exclusive feature claimed for the Jones instruments.

INFORMATION FOR AUTO USERS.

The Fry Adjustable Plug.—The spark plug handled by the T. C. & W. L. Fry Company, Rochester, Pa., is so constructed that it can be readily adjusted without removing any part from the cylinder.

FRY PLUG.

point in a vertical line, giving the hottest spark on the least amount of current.

Wipe Contact Timer.—To meet a demand for a good wipe contact timer the Uncas Specialty Company, Norwich, Conn., has improved upon the standard types of timer by adding a supplementary ground terminal and an adjustable ball bearing in place of the plain bearing.

A BALL-BEARING TIMER.

which will cause skipping when running at high speeds. The above faults are usually ascribed to the plugs, coils or carbureter.

New Type Steering Gear.—A new form of steering gear likely to meet with much success among automobilists has been put on the market by the Briscoe Manufacturing Company. Its features are very slow acting for straight ahead running with increased rapidity of movement as the steering wheel is turned over.

ing column. The internal gear is five-sixths of the diameter of the external gear and gives almost a surface contact, three teeth being always fully in mesh. A cam on the steering spindle fits into a hole through the center of the internal gear, which is pivoted to the casing, and drives it round the external gear by an eccentric movement.

Abell Speed-Meter.—All the parts in this speed indicator are concentric and work about a common center. The indication is shown by means of a pointer and dial similar to a clock, the hand making three-quarters of a circle before it reaches the end of the scale, which is 65 miles on a standard instrument and 100 miles on a special size. The hand is mounted on the top of a stem or pivot on the lower end of which is mounted a cup shaped shell lined with fiber and polished on its inner face, which serves

THE ABELL SPEED-METER.

as a race-way for four small weights in the form of cylinders. These weights are mounted loosely in drilled holes in the rim made disk which revolves about a stationary ball bearing stud and is driven by the flexible shaft. They are provided with polished glass friction points which after a great deal of experimenting, is found to be an ideal material for this use. When the machine is at rest the weights lie idle in their sockets without exerting any outward pressure, but immediately on rotating the disk carrying the weights, the weights themselves begin to move, fly out and press against the polished face of the friction cup. The sliding contact thus set up immediately starts the friction cup in motion, but as it is retarded by a spiral spring, it moves only as far as the friction set up by the centrifugal pressure of the weights will carry it.

The odometer used in connection with this instrument is of standard make and is driven with a small worm and gear by the same shaft that revolves the weights. The instrument is mounted on a pivoted bracket which can be fastened by screws to any convenient part of the dash board,

and can be set at the proper angle so that it may be easily read from the seat. It is manufactured by the E. T. Kimball Company Motor Mart, 87 Church street, Boston.

Putnam Motors.—An interesting series of small four-cycle motors, air cooled and water cooled, with one, two, and four cylinders, is manufactured by R. H. Putnam, of 57 Lebanon street, Springfield, Mass., and castings and blueprints for making these motors are sold also. The list includes a 21-4-horsepower motorcycle motor, with 2.3-4-inch bore and 3-inch stroke, listed at \$40; a double cylinder motor, with cylinders of the same size, placed at an angle of 60 degrees, rated at 41-2 horsepower and listed at \$70; a four-cylinder 10-horsepower motor, with cylinders set at 60 degrees, built to order only; a 2-horsepower, single cylinder, water-cooled marine motor at \$47.50; and a 4-horsepower motor of the same type costing \$75. The list of built-to-order motors also includes an 18-horsepower, air-cooled, and a 28-horsepower, four-cylinder, water-cooled motor. The Putnam motors all have outside flywheels and valves in cylinder-heads operated by long push-rods.

A Puncture-proof Tire.—One solution of the tire problem appears to have been solved by the Puncture-proof Tire Company, 707 American Trust Building, Cleveland, Ohio. The general form of this new tire is indicated by the cut herewith. Best up-river Para rubber, compounded, is used for the body of the tire; the central air space and slit to the base of the tire being lined with layers of friction cloth, coated with a thirty-second of an inch of rubber between the layers of friction for the purpose of giving the tire strength and preventing any tendency of the rubber to crack. The clincher and the lower part of the outside of the tire immediately above the clincher also has layers of friction, covered entirely with rubber. The superior advantage claimed for this tire are a resilience equal to that of the pneumatic, and an entire absence of punctures and their resulting accidents and expense. To fit the puncture-proof tire, the wheel is jacked up and one side of the tire placed in the clincher all the way round; the sewed side is forced in by means of a machine built for that purpose. Thus held, they form a perfectly solid base between the clinchers, but as a further precaution, steel pins are placed in the base through the bead or

CROSS-SECTION PUNCTURE-PROOF TIRE.

clincher of the tire, an inch and a half apart alternating on either side. The puncture-proof tire was on exhibit at Madison Square Garden, but was unfortunately omitted from our account of the show through inadvertence.

THE AUTOMOBILE

NEW YORK—THURSDAY, JANUARY 31, 1907—CHICAGO

No. 5

THE CHICAGO SHOW: ITS ORIGIN AND GROWTH

Exhibition Opening Saturday Next and Concluding February 9 Will Contain More Car Exhibitors Than Any Preceding

BY S. A. MILES, GENERAL MANAGER NATIONAL ASSOCIATION AUTOMOBILE MANUFACTURERS.

AN attempt to outline the history of the Chicago Show of necessity recalls events which, while now regarded by the victim as an excellent joke, were at the time anything but amusing experiences, and required the exercise of the utmost pertinacity on the part of the promoter in overcoming the difficulties presented in those unsettled pioneer days of the industry.

The first show held in the Windy City was an outdoor affair, conducted at Washington Park, on whose classic track Alexan-

der Winton and other celebrities of the racing world of that day performed wondrous feats, considering the development of the automobile at that time, and others undertook performances on movable platforms and other apparatus, designed to impress the public with the idea that the automobile could climb steeples and turn somersaults in the hands of experienced operators. But for reasons into which it is unnecessary to enter, the show was anything but a success. This event, by the way,

AT NIGHT IN FRONT OF THE BIG COLISEUM DURING THE CHICAGO AUTOMOBILE SHOW WEEK.

ARCH REPRESENTING DIVIDING LINE BETWEEN MAIN SPACES.

had no connection with the later one promoted at the Coliseum, which has become, after seven years of experience, at least as important as any automobile show held in the United States.

In the days of the cycle trade's glory the owners of a number of journals devoted to that sport, and published in Chicago, promoted a number of immensely successful affairs. By the time the cycle craze died, and the automobile had commenced to take its place, these same gentlemen had formed a combination for the publication of a journal devoted to the new form of locomotion, and their experience naturally led them to undertake the promotion of an automobile show. They were troublous times, however, for the field of automobile journalism was necessarily limited, so that, by the time the show plans actually matured, only one member of the combination remained to persevere, though thick and thin—the same individual, by the way, who has conducted the Chicago show ever since, and apparently intends to remain in harness so long as automobile shows endure.

The plans of the promoter of the first Chicago show held at the Coliseum seemed to be progressing with reasonably fair prospects when, during the New York show of the fall of 1900, the National Association of Automobile Manufacturers was formed. One of the first things the executive committee did was to adopt a show resolution, which was practically an instruction to its members to take no part in the Chicago event. The promoter of the show finally succeeded in bringing about a special meeting of the committee, and, by convincing them that Chicago's importance as an industrial center and possible automobile market had been underrated, secured the passage of a new resolution which, however, prescribed that all automobile shows thereafter held must be conducted under the auspices of automobile clubs. The automobile club was a far more important institution in the eyes of the few manufacturers of that day than it is at present.

The management of the first Chicago show practically assured the future success of that event by doing one thing which no one

A SECTION OF THE ORNAMENTAL DECORATIVE FRIEZE.

else had previously thought of. Experience with the cycle shows had taught that the man to be appealed to, at that time, was the automobile agent or the person who aspired to become one. Strenuous efforts were therefore made to secure the attendance of men of that class.

From the standpoint of the promoter the show was anything but a success, but from the standpoint of the exhibitors its success was unqualified. One factory, then producing steam cars, sold more than it was able to produce that season.

For weeks prior to the opening of the show the question with the management was not whether it would be possible to get a large number of exhibitors, but whether it would be possible to beg or to borrow enough cars to make a presentable showing. The huge floor of the Coliseum was encircled by a track about twenty feet wide, and by dint of more or less maneuvering the center was finally fairly well filled with an exhibit which to-day might appear to have been produced by the makers of half a century ago. The dealers were there in force, the public at-

FIRST REGIMENT ARMORY, WHICH WILL ALSO BE USED FOR THE SHOW.

tended in sufficiently large numbers to indicate the growing interest, and, despite the financial loss, the event was voted by the exhibitors who participated to have been a highly successful affair, as the prospects were brilliant.

The mandate of the National Association was obeyed to the letter. The second show was held under the auspices of the Chicago Automobile Club, with which organization the promoter concluded a satisfactory arrangement. It is almost impossible to make a comparison between the first and second shows. The main floor of the Coliseum was well filled, and the financial loss of the previous year became a satisfactory gain. The third, fourth and fifth shows showed steady progress. In the third it became necessary to place makers of parts and accessories in the Annex; in the fourth the gallery was added to the exhibition space by flooring over that portion usually devoted to seating. In the fifth the second floor of the Annex was used, which helped to relieve the congestion.

When the time for allotment arrived last year it became evident that a large number of exhibitors must be denied space or more room must be secured. The demand was so far in excess of the supply that it would have been impossible to give each manufacturer room enough to display even a small part of his exhibit. About a hundred yards from the Coliseum, and divided from it by a public alley, stands the First Regiment

Armory. After a great deal of tribulation and settlement with other organizations who had leased it for the same dates as the automobile show, this building was secured and the space was divided, as fairly as possible, among the eighty exhibitors of cars. The gallery encircling the Armory was given up to accessories. Even with this addition, despite the fact that the total floor space available for exhibits was nearly 80,000 square feet, it was still impossible to take care of every one, or to give any exhibitor as much space as he would have liked, in consequence of which a part of the second floor of the Coliseum Annex, previously sacred to the accessories department, was used for the exhibition of automobiles.

This year there was no room for extension, but a few exhibitors who had been unable to secure space discovered a couple of small balconies and requested to be allowed to exhibit therein. This space has already been allotted.

The public interest has kept pace with the production and demand for space by the manufacturers. Without going into the details of attendance, it may be noted that last year the receipts from all sources were little over 50 per cent. greater than in any earlier year, and that so far as could be gathered not less than one hundred and twenty-five thousand people attended.

The conduct of the Chicago show no longer entails any question about financial returns. An endeavor has been made each year to reduce the cost to the exhibitor. The space rental was reduced in 1906, and has been reduced again for 1907. It is estimated, too, that the plan of uniform decoration resulted last year in a saving to the trade of not less than \$50,000.

The efforts of the management are devoted to the presentation of an exhibition which shall be second to none. In the matter of exhibits the attainment of this object is now beyond question. The Chicago show is the first and only national event in which cars of all classes, licensed and unlicensed, are exhibited together. The result is that the number of automobile exhibits is far in excess of that at any other show, the exact number booked for the coming show being 104.

Whether the scheme of decoration and the general setting are equal to those employed at Madison Square Garden is, and must remain, a question to be settled by those people who have an

opportunity to see both. Last year opinions were divided. The plans were so entirely different that the question was one merely of taste. The setting at Chicago this year will be chiefly of staff, and therefore somewhat more massive than that at New York. Pictures and statuary will be used to some extent, but in an entirely different way. One feature of the decoration worth attention is that it relates directly to the automobile industry.

The policy of paying particular attention to the dealers has been consistently followed through all of the Chicago shows. The management recognizes the fact that the shows at New York and Chicago are no longer national in the sense that they once were. Time was when dealers were scarce and independent; when they made their annual pilgrimage to the shows for the purpose of placing their orders for the season. That has all passed. Ninety per cent of the dealers now place their orders long in advance. The shows have, therefore, become, to a great extent, local shows. The dealers attend them in just as large numbers as ever, and they attend the Chicago show in greater numbers than any others, bringing with them prospective customers from all parts of the country.

To the average New Yorker many of the Western dealers are objects of curiosity. They waste no time. During the week hundreds of them, arriving in Chicago by early trains, make their way to the Coliseum without as much as depositing their baggage at hotels, and make demands for admission to the building as early as 8 o'clock in the morning. Before half of the exhibits have been uncovered many a dealer will have spent a couple of hours quietly inspecting the cars before the rush of the day.

MEDALLION DECORATIVE FEATURE.

LOCAL SHOW PREPARATIONS IN VARIOUS CITIES.

BUFFALO'S SHOW PROMISES SUCCESS.

BUFFALO, N. Y., Jan. 28.—Indications at this time point to a successful automobile show for Buffalo in Convention Hall, beginning three weeks from to-day. The management is again confronted with the very serious proposition of making room for all who desire exhibition space, and has been again compelled to cut up the two restaurants at the right and left of the main entrance for the purpose of utilizing them for exhibition purposes. This means that the restaurant will be upstairs during the show. Since the first allotment of space on January 10 several applications from automobile manufacturing companies have been received. Secretary D. H. Lewis is doing his best to satisfy every exhibitor at the show. Concerts will be furnished every afternoon and evening by the Sixty-fifth Regiment Band. Much attention will be paid to the decorations. It has been decided to have the color scheme one of green and white, making a garden effect of Italian characteristics.

DATE SET FOR SAN FRANCISCO SHOW.

The week of February 18-25 has been selected for the first automobile show to be held in San Francisco. It will be promoted by the Automobile Dealers' Association, whose headquarters are at 426 Golden Gate avenue. The Golden Gate Park Skating Rink is the building which will be employed to house the show.

GOOD OUTLOOK FOR PITTSBURG SHOW.

PITTSBURG, PA., Jan. 28.—Nearly \$30,000 worth of space has already been contracted for at the automobile show to be held at the Duquesne Garden in Pittsburg in April. Offices of the show committee have been opened at the Automobile Dealers' Association, under whose auspices the show will be held, at 5917 Baum street, East End, with John P. McCrea in charge. Advance indications point to one of the most successful automobile events ever held in this country.

WESTERN MAKERS TO EXHIBIT IN BOSTON.

BOSTON, Jan. 29.—Interest will be lent to the power boat section which is to be a more prominent feature of the Boston show this year than ever, by the fact that many of the Western manufacturers who will have elaborate exhibits at the Chicago show to be held March 2-9, will duplicate them at the Hub. Greater efforts than ever are being put forth to make the show as a whole the greatest that New England has ever seen.

CLEVELAND PROMISES A BIG EXHIBIT.

Ten days after the close of the Chicago show, Cleveland will put on its annual event, which will be held in the Central Armory along the same lines as last year, except that more elaborate preparations will be made and a larger exhibit staged. The show will open on February 18 and remain open until the 23d.

WASHINGTON'S AUTO SHOW IS OPEN.

WASHINGTON, D. C., Jan. 28.—Resplendent with a multitude of electric lamps, the Dupont garage on M street was thronged with people to-night to witness the opening of the seventh annual show of the Washington Automobile Dealers' Association. They had the pleasure of seeing the most representative collection of cars ever exhibited in Washington, and they lost no time in making the circuit of the two floors of the garage in order to become acquainted with the 1907 models. Washingtonians are getting automobile wise, a fact that impressed every agent. The latter were not bored with a lot of fool questions, as at previous shows, for even the casual visitor had a good working knowledge of automobile construction, and talked intelligently on the subject.

THE AUTOMOBILE correspondent counted 58 cars on the two floors of the garage, 27 different makers being represented. While the number of cars exhibited is somewhat smaller than last year, more makers are represented than ever before. Brisk sales marked the opening night, and it is quite evident from what was done to-night that the show is going to result in good business. The Capital City seems to be in a buying mood, and the agents have been quick to seize upon the opportunity.

The battle-scarred Thomas racer used by Le Blon in the last Vanderbilt cup race, and a Locomobile racing machine, are two interesting features of the show. Both were towed through the streets of Washington this morning en route from the express company's warehouse to the show room, and they came in for a good share of attention. Washington does not have many opportunities to see big racing machines, and this accounts for the unusual interest evinced in these cars. The exhibitors are as follows:

Pope Automobile Company, of Washington; Commercial Automobile and Supply Company, Wayne; Washington Electric Vehicle and Transportation Company, Columbia; the Cook and Stoddard Company, Pierce Arrow, Franklin, White, Baker, Cadillac; Motor Car Company, Peerless, Stevens-Duryea, Thomas; National Automobile Company, Buick, Studebaker, Oldsmobile; Dupont Garage Company, Waltham-Orient; Geo. P. Sacks, Rambler, Cleveland; Chas. F. Fleming, vehicle clocks; Automobile Tire and Repair Works, tire repairs; Auto Supply and Storage Company, Holsman, Logan; Chas. C. Hughes & Co., Elmora; Carter Motor Car Company, Cartercar; Hamilton Auto Company, Stoddard-Dayton; National Electric Supply Company, tires, lamps, etc.; C. W. Hamilton, American Mercedes; Rudolph, West & Co., tires, lamps, etc.; Chas. E. Miller & Bro., Reo, Ford, Columbus electric; Electric Storage Battery Company, Exide batteries; Pennsylvania Rubber Company, tires; F. N. Cycle Company, F. N. motorcycles; J. R. Thomas, Maxwell.

BALTIMORE SHOW CLOSES ITS DOORS.

BALTIMORE, Jan. 26.—After drawing big and enthusiastic crowds to the Lyric for six successive nights the lights were turned out this evening on the second annual automobile show of Maryland, and the exhibition unanimously voted a success. Sales on the floor of the hall were not as numerous as they might have been, and as many hoped they would have been. But an automobile show is as much an evangelizing as a selling ground, and the full benefit of the public display is certain to be felt in the shape of a rush of orders during the early spring.

Family interest in the exhibits was a feature of the show; the farmers, too, who are popularly supposed to nurse a respectable amount of antipathy to automobiles, showed themselves interested in those types of machines likely to prove of use for their particular class of work. The cinematograph exhibition, with its realistic scenes from the Vanderbilt Cup race, and other automobile events always kept captive a crowd. Local opinion is in favor of holding the show on an earlier date, the beginning of December being put forth as a suitable time.

The accessory men held both sides of the hall, the main floor being occupied by the exhibitors of cars.

MECHANICAL BRANCH A. L. A. M. TO MEET.

In order to extend the scope of observation that was open to the members of the Mechanical Branch of the Association of Licensed Automobile Manufacturers at the show held by the latter in the Garden, it has been decided to hold a meeting during the Chicago Show. This will take place on February 6, at the Chicago Athletic Club, the chief object being to give the engineers an opportunity to inspect the cars of the exhibitors at Chicago who are not members of the association, as well as to compare them with those that are, as in a great many instances they will be shown side by side. The subjects to be considered will be shock absorbers and carbureters, clutches and springs, and in accordance with the plan adopted for the first time at the January meeting in this city, it has been decided to invite representatives of the leading makers of such parts. Judging from the results attendant upon the latter it is anticipated that considerable of interest will be brought to light, as the manufacturers are given an opportunity to put forth their side of a subject with which they are thoroughly familiar.

COMMITTEE'S REPORT ON THE GARDEN SHOW.

On Friday last, the Show Committee of the Association of Licensed Automobile Manufacturers met in this city to consider the results of the show recently held in the Garden, and formulate plans, based on these results, for the show next year. According to the statement of the press agent, orders to the extent of \$3,000,000 were placed during the week, of which \$937,000 were for imported cars. The records of the committee showed that the attendance for the week was 125,000. On Tuesday, which was one of the worst days of the week considering the weather, the attendance was 20 per cent. greater than for the corresponding day of the year previous despite the doubled admission fee. High water-mark was reached on Wednesday, with an attendance of 21,000. The Show Committee is of the opinion that it will be necessary to increase the general admission to \$1, and make this \$2 on one or two days of the week. Plans are already under way to increase the floor space of the Garden by an additional 15,000 to 20,000 square feet. One of the most noticeable features of the show was the decreased necessity for demonstrations to make sales, and it is thought that in the near future the matter of demonstrations will be done away with altogether.

MARYLAND AUTOISTS HAVE GRIEVANCES.

BALTIMORE, Md., Jan. 28.—Strained relations between the automobilists of this city and the police, owing to the activity of the latter in enforcing the twelve-miles-an-hour speed limit, have caused the Automobilists' Protective Association of Maryland to issue an address to the public. In it they point out the injustice and absurdity of the law, and claim that the only restrictions the State can reasonably impose upon the drivers of automobilists are those which tend to conserve the safety of the public. The police, in an effort to put a stop to reckless driving of automobiles by a comparative few, have undertaken to enforce the existing law without regard to the evident purpose for which it was intended, and in such a manner that it is no longer possible for any automobilist, no matter how considerate he may be, to use the streets of Baltimore without constant dread of being arrested for some technical or trivial violation of the law which in no way endangers the safety of the public.

The association is also having trouble with the police over the law compelling drivers of automobiles to sound their horns or sirens at all street crossings. Arrests for neglect of this rule have been numerous, and finally the Protective Association has decided to test the law. President Osborne I. Yellott contends that there is a defect in the present automobile laws of Maryland, in that the section pertaining to the sounding of horns applies to the counties only, and not to the cities.

ORIGIN AND RISE OF THE N. A. A. M.

THOUGH but little more than six years have elapsed since either shows or organizations of automobile manufacturers came into existence, the early history of both is surrounded with more or less of a haze—so much so that few outside of those who actually participated in the small beginnings that have grown so vastly can state to a certainty whether a trade organization was responsible for the first show or vice versa. But this doubt can at once be set at rest when it is recalled that during the holding of the first show in Madison Square Garden a call was issued to “manufacturers of motor vehicle supplies and accessories” to come together and formulate plans for an association “to advance and protect the interests of the trade, procure lower freight rates, more equitable legislation, protest against the adverse and unjust ruling of the Treasury Department, hold shows and exhibitions and give attention to such other matters as required attention.” These are not the exact words, though they represent more than an expression of the substance of that first notice.

Press Room, Scene of First Meeting.

In response to this call a number of manufacturers of cars and parts, and dealers in accessories assembled in the press room of the Garden on November 10, 1900. John Brisben Walker was appointed temporary chairman, and Ralph Estep temporary secretary. The organization committee consisted of S. T. Davis, Jr., Charles E. Miller, A. L. Riker, W. C. Baker, E. P. Wells, John Brisben Walker, Charles E. Duryea, J. M. Hill, Alexander Winton, C. J. Field and A. S. Winslow. By a resolution this organization committee was continued as the executive committee of the association. The chief business at this first meeting was naturally the matter of completing the organization, and to this end a committee to draft a constitution and by-laws was appointed by the chair. It was composed of A. L. Riker, Charles E. Duryea, Charles E. Miller, A. L. Winslow and E. P. Wells. At the same time the chair appointed a committee to take in hand the matter of legislation, which, even at that early day, gave promise of proving a vexatious problem. This consisted of Colonel Albert Pope, A. L. Barber, John H. Flagler, S. T. Davis, Jr., and Alexander Winton. The purposes and aims of the association were drawn up in the form of resolutions to which all intending members subscribed. Taken in the light of present-day knowledge, the list is one that mutely expresses a great deal of the history of the development of the automobile in this country. To those who are familiar with what has intervened it speaks for itself. The companies or concerns who were present individually or sent repre-

M. J. BUDLONG

THOMAS HENDERSON

WINDSORT I. WHITE

C. C. HILDEBRAND

WM. E. METZGER

N. A. A. M. SHOW COMMITTEE.

sentatives and who signed the resolutions, were as follows: The Mobile Company, Joseph Dixon Crucible Company, B. F. Goodrich Company, Charles E. Miller, Crescent Auto Manufacturing Company, The Steam Mobile Company, C. J. Downing, Goodyear Tire and Rubber Company, Winton Motor Carriage Company, Haynes-Apperson Auto Company, Locomobile Company of America, Duryea Power Company, Overman Auto Company, International Motor Car Company, Upton Machine Company, Munger Vehicle Car Company, Veeder Manufacturing Company, Gray & Davis, New York Motor Vehicle Company, Peerless Manufacturing Company, Motsinger Device Manufacturing Company, St. Louis Motor Car Manufacturing Company, Waltham Manufacturing Company, Baker Motor Vehicle Company, De Dion Bouton Motorette Company, Riker Motor Vehicle Company, Electric Vehicle Company, Knox Automobile Company, Baldwin Cycle Chain Company, and the following publications: the *American Automobile*, the *Motor Vehicle Review*, the *Cycle and Automobile Trade Journal* and the *Motor Age*.

Charter Members Still Prominent.

Considered from any point of view, such an array of interests would have formed an imposing list of charter members for any association representing an entirely new industry to begin existence with, but when taken in the light of the development of the automobile at that day, the showing is truly remarkable and reveals the demand for co-operation that must have existed.

The foresight of the organizers of the association as shown by many of the names of this original list of members, is not only justified by the remarkable development of the industry as a whole in the intervening years, but the prominence to which many of them have attained in that time. Some of the names have changed, and more have dropped out of sight altogether, but the great majority of them have always formed the foundation of the industry as well as its representative association where the builders of cars have been concerned, as well as providing a nucleus for the formation of an association of accessory makers and dealers which has since come into existence as an offshoot from the original organization.

A second meeting was held at 11 Broadway, New York, on December 7, 1900, and at this the following officers were elected: President, S. T. Davis, Jr.; first vice-president, J. H. Flagler; second vice-president, J. Wesley Allison; third vice-president, C. J. Field; secretary, E. P. Wells, and treasurer, David Walker. It was decided that the executive committee should consist of fifteen members, divided into groups of five to serve for one, two and three years respectively. The follow-

ing were elected to serve one year: S. T. Davis, Jr., Henry F. Bradbury, A. S. Winslow, Charles E. Duryea, C. B. Frayer; to serve two years, J. M. Hill, A. L. Riker, W. C. Baker, J. H. Valentine, Henry H. Flagler; to serve three years, J. B. Walker, C. J. Field, E. P. Wells, J. Wesley Allison, and Alexander Winton.

Not a little of the history of the growth and development of the automobile industry as a whole is discernible by merely running over the list showing the names of the officers of the association that succeeded each other year after year. This is particularly true of the first years of the organization's existence, when its very name was synonymous with the American automobile industry at large. For instance, at the second annual meeting for the election of officers, which was held at the office of the Locomobile Company of America, at 7 East Forty-second street, S. T. Davis, Jr., was elected president; A. L. Riker, first vice-president; C. J. Field, second vice-president, and D. E. Rianhard, third vice-president; E. P. Wells, secretary and Percy Owen, treasurer.

At the third annual meeting, which was held at the same address, on February 4, 1903, the following were elected: M. J. Budlong, president; H. Ward Leonard, first vice-president; Windsor T. White, second vice-president; Charles Clifton, third vice-president; Percy Owen, treasurer, and Harry Unwin, secretary. The fourth annual meeting was held at the Madison Square Garden during the course of the fourth annual show on January 23, 1904. It resulted in the reelection of M. J. Budlong as president; first vice-president, Windsor T. White; second vice-president, Charles Clifton; third vice-president, E. H. Cutler; treasurer, W. R. Innes, and secretary Harry Unwin. The fifth annual meeting was held at the Hotel Victoria in New York on January 18, 1905, at which the entire set of officers of the year before was unanimously reelected.

What the Association Has Accomplished.

It would be difficult to give a comprehensive review of all that has been accomplished in the past six years as the result of the coöperation of some of the most prominent manufacturers in the early days from which the national association grew. Within two years after its formal organization at the first automobile show in the Garden in this city, it lent its support to the holding of an annual show in Chicago, which has grown and flourished no less than its forerunner, as have also the shows held in smaller cities. On this account the association has been largely identified in the public mind with the matter of shows, though a vast amount of equally important work has been carried on that does not reach the public ear. For instance, four years ago a standard warranty was established and adopted, and though it has frequently been a matter for discussion, it has not been changed in any way during that time. Most of the makers print this guarantee in their catalogue, and a great many who are not members of the association have adopted it. At first sight this may appear to have been merely a measure of self-protection, and of no particular interest apart from that, nor of any far-reaching significance, but it is one of the things that reflects the moral influence that the National Association of Automobile Manufacturers has constantly wielded over the industry as a whole. Bearing in mind the rapid rise and decline of the industry that immediately preceded—the making of bicycles—every effort has been directed to avoid any tendency toward over-inflation; the boom idea has been consistently and persistently frowned down, and the members urged not to attempt to make a greater number of cars than they could make well, and in this manner the growth of the industry has been natural and on sound financial lines—a fact that is reflected in the standing of those makers who are members of the association.

Besides this, the association has interested itself in everything pertaining to the advancement of the industry generally, as well as of the interests of its members, and be it said to its credit, the latter have not been allowed to overshadow the general good. It has always taken an active interest in legislation

in any way concerning the autoist, and its policy in this respect has been consistent, in that it has exerted every effort to prevent meddling with laws that were reasonably acceptable, as well as to block the passage of unreasonable legislation in any form. Its interest has gone further than this. With the firm belief that most of the automobile legislation is based upon fundamentally wrong principles, it has instituted an action to test the constitutionality of State licenses, and has already carried it through several of the lower courts of New Jersey. It will be taken, in due course, to the Supreme Court of the United States, and even though the contention of the association be decided against, the matter of a single State license being sufficient anywhere in the country will have been passed upon at the same time, as this is also being contended for. During 1905 it lent financial aid to the proposed free alcohol legislation. In the matter of good roads also, the association has always been very active, and a great deal of benefit has resulted, and will continue to come from the work that is constantly being carried on with the improvement of the highways in all parts of the country in view. Instances of the good work that has been carried on by the association might be multiplied indefinitely, and through it all may be seen the beneficent influence that such an organization, when well managed, may wield for the good of the industry it represents.

COURT PRONOUNCES ON FOREIGN REPAIRS.

WASHINGTON, D. C., Jan. 28.—The United States Circuit Court of Appeals for the second circuit has rendered a decision favorable, in part, to the importer, in the case of *J. T. B. Hillhouse v. United States*. The case came before the court upon appeal from a decision of the Circuit Court for the Southern District of New York, affirming a decision of the Board of General Appraisers, which sustained the Collector of Customs at New York in assessing duty upon an automobile of foreign manufacture under the tariff act of 1897. An automobile owned by Mr. Hillhouse was used abroad more than one year, and was subjected to extensive repairs shortly before importation. The court held that so much of the machine as was a new manufacture (new parts, reupholstering, etc.) was dutiable, but that the rest, including the cost of overhauling, oiling, cleaning, readjusting and regulating, was free of duty under paragraph 504, as household effects used abroad more than one year.

SCHROEDER'S "DIXIE" TO COMPETE ABROAD.

Commodore Edward J. Schroeder, of the Motor Boat Club of America, has challenged last year's winner of the Harmsworth trophy, which means that the *Dixie* will compete in the international contest the coming summer. The *Dixie* is the star boat in this week's races at Palm Beach, Fla., where she outclasses all rivals in point of size and speed.

The Motor Boat Club of America has just been advised of the fact that the British race will, in all probability, be held during the first fortnight in August and the course will be inside the Isle of Wight. The course last year was a triangular one just inside Southampton waters and the same will, in all probability, be adopted for the race this year.

WHY WAGNER CARRIED AN ARSENAL.

After fourteen days in New York, Louis Wagner, the Vanderbilt victor, last week returned to his native land on *La Gascogne*. A little adventure on the eve of sailing almost caused Wagner to miss his passage. Held up by a New York policeman for speeding, the Frenchman was discovered on being searched at the police station to be the possessor of a revolver and a big knife. His explanation of the presence of the forbidden arms was that he had bought the revolver to protect a large sum of money he was carrying back to France, and the knife was one he regularly used to rip off punctured tires. Evidently the explanation satisfied the authorities, for the case was dismissed and Wagner was able to sail as he had intended.

LOCATIONS OF THE CHICAGO EXHIBITORS

ALTHOUGH such seldom appears to be the case to the casual observer, systematic arrangement and order are the keynote of every automobile show. It may look at first sight as if the exhibits were hopelessly jumbled and as if confusion reigned supreme, the only way of locating a certain exhibitor being to go on a blind hunt in the hope of stumbling across his location by dint of luck and perseverance, and generally this is the plan followed by the average seeker after information of this nature. And confusion is worse confounded when he calls others to his aid, for the query, "Where is Blank's stand?" either brings no information or much that is misleading. For this reason the appended classified list of exhibitors will be found valuable.

THE AMERICAN AUTOMOBILE

D OUBTLESS there are few, even though closely connected with the industry—in fact, a part of it—and cognizant on that account of all that happens concerning it, who appreciate the vast strides it has been making, or realize on what a solid foundation this growth is based. There is presented, in tabular form in the following pages, for the first time in the history of the industry, a résumé of the cars, the annual output of which, mounting into the thousands, goes to swell the vast total that has served to place America in the front rank, where the number of cars in use is concerned, despite the fact that she was among the last of the principal manufacturing nations of the globe to consider the automobile seriously, and when she did take it up, persistently barked up the wrong tree for some time. An attempt has been made to present in tabular form for easy reference, a list of all the cars made in this country, grading them according to their selling price alone, so that, taken as a whole, the table may be said to be representative of the American automobile. It is not contended that the list is as complete as it can possibly be made; doubtless, there may be some makers who have been in business for some time who have been inadvertently overlooked, while in other cases, cars that are listed have ceased to be factors, except in the hands of those few purchasers.

An analysis of its most salient features shows better than

anything else can the trend of things in the automobile field, as well as revealing in a manner little short of marvelous the great expansion it has undergone in the past year or two. The first page of the table brings to light in no uncertain manner the fact that while the "poor man's automobile" may not be a reality as yet, it is not because there is no one bending an effort toward that goal. The extent of the list of cars of all types that are now made to sell at less than \$1,000 must come as a surprise to those who have always regarded the automobile solely as the perquisite of great wealth. And this must be further intensified by the even greater showing of cars made to sell between \$1,000 and \$2,000, while going a little further reveals the fact that probably more automobiles of the modern, high-powered type are listed at \$2,500 than at any other single figure. More than this, it shows that the efforts of American manufacturers are not confined to catering to any one class where style or power is concerned; cars are being turned out in large quantities at low figures, but, on the other hand, the American maker has also soared, and automobiles made in this country are now to be had at prices as high as any demanded abroad. In the field of the electric pleasure vehicle, and of the commercial vehicle, both of the electric and gasoline-driven types, the great expansion that is constantly taking place is equally plain.

CHICAGO A GREAT AUTOMOBILE CENTER

CHICAGO, Jan. 28.—To-day Chicago, the metropolis of the West, stands out as a great automobile center. The industry here has spread to such an extent in the past few years, in a remarkably short time, in fact, that it is recognized the country over as second only to New York in this respect. And in many ways it does not have to bow the neck even to the Gotham city. A casual visit to the district of this city designated as "automobile row," from Twelfth street to Sixteenth along Michigan, would be more than enough to demonstrate to anybody that such is the case.

The industry here has grown and extended by jumps until it forms no small part of the city's greatness. Nothing is done by halves in this thriving center of business, and this extends over every phase of industry. When it is said that nearly one hundred automobile firms are situated here within a comparatively small radius, the extent of the business done can be determined in a vague way. Chicago is essentially a distributing point as regards automobiling, yet it is coming along rapidly as a manufacturing center of cars. In a few years it is probable that many large factories of reputation will be centered here.

By virtue of the city's situation comes its adaptability as a distributing point. It supplies the Northwest, the West, in some cases as far as the coast, and in others to Denver, the Southwest and the South. Most of the manufacturing companies have their Western agents here, who in turn allot the different territories to other agents throughout the country. Moreover, Chicago is near the center of the manufacturing district, Detroit, Michigan. All of these advantages have placed Chicago in the position which it now occupies in the automobile world.

In the city itself there is a great deal of business done. Thousands and thousands of automobiles are owned here, and the presence of so many wealthy men makes the industry a permanent one. Taking all of these considerations together it is not surprising that the large number of dealers have become pressed for quarters in so short a time. Firms have moved in here with small accommodations, have extended them in the course of a year or so, repeated the process, and are now at a loss what course to pursue. Rents along Michigan avenue have been doubled in most cases in the past five years, due to the persistency in which the automobile dealers have been grouping together.

This grouping of the dealers forms an interesting page in the history of the industry's growth in Chicago. Some few years ago Wabash avenue was "automobile row." There were but few firms here in those days, and they extended all the way from Adams street on the north, to Harrison or Peck court on the south. Then three firms, the Winton, the Locomobile and the Woods took quarters on Michigan avenue in the neighborhood of Twelfth and Thirteenth streets. Others finding that situation an ideal one from a business standpoint, being on a well-paved street and away from the loop district, began to follow the pioneers' example, and one by one they moved into adjoining quarters, until now but two or three remain on Wabash avenue, and they will probably vacate in the near future. Thus was the new "row" brought into existence and extended.

As new firms came in they also took their station on Michigan avenue, until now the "row" is not bounded by Twelfth and Seventeenth streets, but by Harrison and Twenty-second streets. In fact, but a few days ago a firm, whose name was not given out, has taken a lease of property at 2223 Michigan avenue. In time this whole line will probably be devoted almost exclusively to the automobile and allied interests, the gaps filling one by one.

Another indication of the extent of the industry here is the large number of dealers in accessories now established here. In some cases firms have built entire buildings, using a part of them for their own use and renting out the remaining portion. This is especially the case of some of the tire dealers. Anything that pertains to the automobile can be purchased here in large quantities, and Chicago is also the distributing point of most of these big firms.

The fact that Chicago has come to be regarded as an automobile center attracts thousands of would-be buyers here every year, and especially has this been the case during the season just passed. Hotel men have emphasized the fact that large numbers of their customers have come here for the express purpose of looking over cars with an idea of purchase. Some come from as far south as New Orleans, and it is not at all startling when a man arrives here from San Francisco or even Mexico City with that end in view. The salesrooms of the dealers are thronged with interested persons daily, and the demonstrating cars are kept in use all the time.

One fact alone which assists the spread of automobiling here in the city, is the presence of excellent boulevards, park systems and country roads surrounding the city for a radius of fifty or seventy-five miles. Side trips to such places as Joliet, Aurora, Hammond, Ind., Kenosha, Wis., and various summer resorts, keep the interest in automobiles up, and stimulates local citizens to purchase cars.

An institution which has also boosted the trade conditions here is an association, formed among the dealers themselves, called the Chicago Automobile Trades Association. This body is formed for the purpose of promoting automobile events that will bring the game before the notice of the public. Hill climbs, endurance runs, economy tests and the like come within its province, and it has already stimulated the game here to a marked degree. It works in harmony with the Chicago Automobile Club, which is essentially a social organization.

The Chicago Automobile Club has done a great deal toward making automobiling in Chicago such a distinct success. It has grown to be a leader in automobile affairs throughout the country, and perhaps ranks second to the organization at Gotham City. It has promoted mammoth meets in the past, and has made a specialty of runs and tours to towns and cities in the neighborhood of Chicago. It is the presence of such a splendid body as this that has helped in a great measure to make Chicago a real center of automobiling.

Aside from business features the situation of this great city makes it such that it is the natural point for the touring autoist to head for. Long runs from New York to Chicago have been frequent, and also from Chicago to the Eastern city. Transcontinental tourists pass through the Windy City, and parties from all over the country, in fact, make it their halting point. These people find Chicago an ideal spot for the automobilist. Both from a social and a business outlook Chicago stands out preeminent, and, what is more, it has a future than can scarcely be conceived of.

In many respects its future appears now even greater than that of New York city, due mainly to its location. New York is too far from the western cities to make much of a mark there, but Chicago, standing midway, as it were, has the country to conquer. The citizens of Chicago recognize this fact, and so do the civil authorities. Much attention is paid to the affairs of the autoist, and his claims are looked into carefully. The city recognizes the fact that a decided interest in automobiling is bound to help the city in more ways than one, and will do everything to foster it.

HONEYCOMB RADIATORS—THEIR CONSTRUCTION*

By L. BAUDRY DE SAJNIER IN OMNIA.

In a preceding article a description was given of the construction of a winged-tubed radiator like that used on the winning car in the last Vanderbilt race. In the present study, the other kind—the honeycomb radiator—will be considered.

The honeycomb radiator would be perfect if it did not leak. It has a considerable radiating surface, for it offers in a small space an enormous surface of exchange of temperatures between the water and air; in other words, it has the power *par excellence* of rapidly lowering the temperature of the water circulating within it. But when it is constructed entirely by hand it becomes

FIG. 1.—Honeycomb single radiator tube, actual size.

a precarious apparatus, for the simple reason that, being composed very often of five or six thousand elements, which ought to be soldered together, it cannot escape human imperfections; a little solder missing here and there through stupidity, carelessness or awkwardness of a workman, and you have a detestable apparatus. The imperfection may be discovered during the tests. But more frequently the hand-made honeycomb radiator is watertight when first tested, and only develops a chronic leak when it has undergone a little road shaking.

Hand soldering is the first honeycomb vice. The manner in which the tubes are assembled is often the second. It is impossible to deal here with all the methods of uniting honeycomb radiator tubes. Among them are many which simply join the

FIG. 2.—Front view of tubes in position.

FIG. 3.—Sectional view of tubes cut in center, showing water circulation space.

parts together by soldered points. Large, flat surfaces should, on the contrary, be employed, so that the complete radiator forms, as it were, a hollow block in which have been bored an infinite number of small channels for the passage of air. In this metal block, the form of which may be varied infinitely, the water enters from above and passes downwards, zigzagging between the small tubes through which air is drawn by the revolving fan in their rear.

As will be seen, the tubes are separated one from the other by a space of one or two millimeters, to allow the water to circulate. Some constructors obtain this separation by two thin, perforated plates, each of which carries an end of the tubes in front and behind. Solder is run round the head and tail of each tube.

In one of the best French radiators, the Establie, employed among others on Panhard automobiles, a different and simpler method is followed. Copper tubes 3-10 millimeters in thickness are used. They are fluted into a shape somewhat resembling a

Maltese cross (Figs. 2 and 3), with a view to increasing the air and water surface. These tubes have a uniform length, Fig. 1 being a full-sized drawing of a 3 1/4-inch tube of 3/8-inch side measurement.

It is necessary to change these fluted tubes, so that their ends shall touch, while their bodies remain separated, for the necessary passage of water. By means of a special machine the fluted end of each tube is opened out to give it a square form, as in Fig. 4. The constructor has now a number of tubes, the two extremities of which are larger than the body, so that when assembled the ends only touch. No cage, platform or network is needed to consolidate the tubes. This form of construction unites simplicity and solidity, for it gives to the extremities of the tubes very large contact surfaces, as is shown in Fig. 2.

The tubes are placed side by side, and built up brickwise. In addition to greater strength, the efficiency of the radiator is increased by this arrangement, since it causes the water to descend in zigzag instead of in a vertical line. The horizontal surface of each tube is also more efficiently utilized.

FIG. 4.—Square end of tube.

Should one of the tubes spring a leak, which is very improbable, a repair can be readily made. A smaller size tube is pushed within the defective one (Fig. 5), and its fluted sides flattened out with a screwdriver or a piece of wood, assuming the form shown in Fig. 4.

FIG. 5.—Repair of broken tube.

Automobile bonnets and radiators have, as everybody knows, a variety of shapes; the united tubes should therefore have the outline necessary for the type of car on which it will serve. The bundles of tubes are locked up in iron frames (Fig. 6) very similar to the chases used by printers all over the world for locking up their forms, fitted with an inner metal frame cut out to the shape of the automobile hood. When locked up, the frame is placed on a flat surface, and one of its faces soaked in a bath of chloride of zinc. By means of the four bars shown in the engraving the frame is placed in the longitudinal opening of an oven (Fig. 7) and the ends of the tubes dipped into a bath of molten metal. The dip should be long enough to allow the soldering metal to penetrate between all the joined surfaces, but not so long as to cause any deterioration of the tubes. The frame is withdrawn, turned over, and the opposite end of the tubes treated in the same manner. The block of the radiator is now formed; all the soldered surfaces have necessarily the same force. After a thorough washing in water, the block of tubes is fitted into a metal frame, forming water tank. This reservoir is provided with suitable divisions forcing the water to descend through the whole series of tubes.

FIG. 6.—Tubes assembled in frames before soldering.

* Translation, by W. F. Bradley. A continuation of the subject of "Radiators," published in "The Automobile," November 8, pages 609-610.

FIG. 7.—Side view of oven equipped with soldering bath.

Before being put into service each radiator is tested in the same way as a pneumatic tire. The outlet is corked up, a rubber tube fitted over the inlet, and the radiator put into a tank of water. Air is pumped in, and if no air bubble rises to the surface of the water the radiator is passed as fit for service.

Radiators vary in width and height, according to the size of the engine for which they are intended. In addition, the length of the tubes varies between three and six inches, their sectional area being correspondingly increased or decreased. It is generally admitted that a half-meter square of radiating surface is necessary per one horsepower for a four-cylinder motor. For a monocylindric or a two-cylinder engine the amount would have to be increased; for a six-cylinder engine it could be decreased. Between 10 and 50 horsepower this formula is generally exact.

Beyond certain limits the increase of the external area of the radiator is an impossibility. A large radiating surface must then be obtained by making the tubes longer or more numerous, thus increasing, within the same external area, the amount of metal coming in contact with the water and air. The longer and thinner the tubes for a given external area, the greater the cooling power. French constructors generally employ tubes about 3-10-inch side measurement. Certain Italian builders have taken much smaller tubes in order to augment the radiating surface, but experience has shown that very small tubes offer a serious resistance to the passage of the air, and that they are apt to choke with dust and mud.

A standard French honeycomb radiator for a 14-horsepower engine consists of about 2,000 tubes 3 7-8 inches long. A radiator for a 35-horsepower engine contains 5,000 tubes. One thousand small tubes 3 7-8 inches long hold within them about 1 4-5 pints of water. A bundle of large section tubes holds a quantity of water equal to about half the volume which it represents.

The method of soldering employed on the radiators just described is far less susceptible to heat than is generally imagined. Thus the cooling water could be drawn off and the engine run until the cylinder heads are a bright red (800 degrees) without the radiator showing the least sign of melting.

FIG. 8.—Radiator that withstood overturn of car. The tubes were uninjured.

notwithstanding its proximity. The layer of air between the engine and radiator is such a bad conductor of heat that it would never communicate the 300 degrees necessary to melt the solder. If a radiator were frozen, a soldering lamp could be passed over its surface without danger. The ice would change into water, and, if the experiment were continued, into steam, but the lamp would never be able to give sufficient heat to melt the solder.

As an instance of the solidity of this type of radiator, Fig. 8 will be noted with interest. The car on which this radiator was fitted overturned into a pit. The lugs and water inlet were broken off, the reservoir rendered practically useless, but the tubes remained intact.

A NOVEL SLIDING GEAR CONTROL.

A rather interesting departure from previous systems of sliding-gear control is that used for the first time on the 1907 Franklin cars, the arrangement being that shown in the illustration. As is well known by every one who is experienced in the manipulation of a gear of this character, the necessity for manipulating the latch in passing from one speed to another is the chief point in which the progressive system of gear changing is less desirable than the selective system, and doubtless accounts for much of

▲THREE VIEWS OF FRANKLIN SELF-FINDING GEAR SHIFT.

the increasing vogue of the latter. By the Franklin construction, manipulation of the latch is required only in passing from the intermediate to the high or low speeds and in passing from the low to the reverse. All other changes are effected simply by pushing or pulling upon the lever, without unlatching. To secure this result, no complication of mechanism is involved, the alteration from the construction previously used consisting of nothing more radical than a beveling of the edges of the notches on the sides from which the lever is required to move without manipulation of the latch. An ordinary plain sector is used, with notches—from front to back—for high, intermediate, neutral, low, and reverse, as shown in the drawing.

GROWTH OF THE FRENCH INDUSTRY.

The French automobile industry during the last year has continued to make remarkable strides. Some idea may be gathered of the progress made by a compilation of the statistics of exportation, which have just become available, which show that the exportation of French machines during the first nine months of 1906 exceeded those for the corresponding period of 1905 by 33,841,000 francs; the total exportation amounted to 126,451,000 francs, against an importation of foreign cars of only 7,150,000.

LETTERS INTERESTING AND INSTRUCTIVE

A Trouble with Peculiar Symptoms.

Editor THE AUTOMOBILE:

[550.]—Will you kindly aid me in the following question: I have a standard double-opposed runabout made by a prominent New York firm, jump spark ignition, water-cooled. After one of the periodical trips to the factory for repair, it was returned with its present trouble; the makers, after expensive experimental attempts at repair, return it in the same condition, look wise, and say nothing, but charge promptly. The car runs well on the floor, noiselessly and with regular explosions at all speeds, with throttle and spark in any position. It does the same in running at slow speed (planetary). At high speed (direct drive) it runs well, with the spark retarded, irrespective of the quantity of gas allowance. The moment, however, the spark is advanced, a pounding results in one cylinder, and advancing spark still more, in the second cylinder. If, however, I advance spark very gradually there is no pounding whatever. Again, driving at high speed, with gas throttled, and spark gradually advanced to the maximum, it runs well; however, on the moment of allowing a trifle more gas, immediately the pounding commences, and continues till the car gains a fair speed, then the pounding ceases. The pounding is one of pre-ignition, as it is the same when the spark is too far advanced. The car is new and has run less than four months, and is of 1906 make. All bearings in motor are snug; storage battery; compression good; valves newly ground; spark is rich; timing apparently correct; exhaust piping clean. Moved easily on the floor by hand; cranked easily with stopcocks open. What causes this apparent lack of power?
A SUBSCRIBER.

Chicago, Ill.

Though you state the symptoms of the difficulty with your car with considerable fullness, they nevertheless fail to enable us to make a positive diagnosis, so we shall have to confine ourselves to a few general suggestions, leaving it to the ingenuity and experience of our readers to discover perhaps the detailed nature of the trouble that confronts you. Our first suspicion, which we have hopes may be confirmed by further investigation upon your part, is that there is nothing the matter, unless possibly a slight variation in the timing between the two cylinders. This condition may, however, be complicated by positions of commutator contact slightly ahead of what they should be at all speeds. Our reason for these theories is that most of the phenomena, as you state them, are perfectly normal for a motor of ordinary type. You say that "the car runs well on the floor, noiselessly and with regular explosions at all speeds, with throttle and spark in any position." This is all as it should be, if we assume that it is because of the flexibility of the unloaded motor that it changes "imperceptibly and without pounding to adapt itself to changes in spark and throttle conditions. Likewise, "at slow speed," it should run without pounding. The fact that at high speed "it runs well, with spark retarded," seems to indicate that the interconnection between spark lever and commutator is in such condition of adjustment as to make the spark appear greatly advanced when it really is not so advanced. In the next three sentences of your letter you describe only the normal action of any motor, with one reservation, when the ignition is advanced too quickly under load. The reservation refers to the difference in time between the commencement of pounding in one cylinder and its commencement in the other. This may be taken as evidence of the previously suggested minor maladjustment within the commutator itself. Look more carefully for some sign of this condition, drive without attempting to produce sudden acceleration by spark manipulation, and watch this column for the opinion of some bright reader who may be able to show us we are both wrong, and we venture to predict that your troubles will soon be at an end. In your final question we note that you refer to an "apparent lack of power," which you do not mention elsewhere in your letter. Do you simply assume from the other considerations you mention that such lack of power exists, or is it definitely a fact that the engine does not "pull?"

The Characteristics of Hot-wire Ignition.

Editor THE AUTOMOBILE:

[551.]—In the course of reading various material that has appeared in the trade periodicals and the various volumes that have been devoted to gas engineering, I have run across various references to "hot-wire ignition," but nowhere have I been able to find a description of such an ignition system, or any extended statement of its advantages and disadvantages. So, as a subscriber to and an interested reader of "The Automobile," I venture to ask if you will devote some space in your columns to an exposition of this subject, in which I believe others as well as myself are apt to be interested.
CLINTON L. HARGREAVES.

Hot-wire ignition has never found more than occasional or experimental application to gas engines, and we know of no case of its application to automobile engines, so it is only natural that it should not have achieved extensive treatment in the literature of the subject. In the only instance we can recall of its use, it took the form of a platinum-wire cage, maintained at a cherry-red heat by the passage of an electric current through it. As in the case of the better known hot tube, the contact of the mixture with the heated surfaces brings about ignition very effectively at the moment of such contact. Unlike the hot tube, however, in which the very construction itself is such as to make any similar protection unnecessary, the hot wire must be shielded by some sort of movable shield in the ordinary type of internal combustion motor to prevent ignition during the suction of compression stroke. Besides this difficulty of timing hot-wire ignition, there is the materially greater current consumption to be reckoned with. It has been proposed, with a prospect of success that may be very real within a year or two, to combine certain modification of the present cycles of internal combustion engine operation with the use of an ignition system involving only a very short and small diameter wire, kept hot by a storage battery or dynamo current. The slight increase in current required, it is argued, would be more than offset by the elimination of coils, vibrators, commutator, etc., none of which can very well be claimed to make for either simplicity or reliability, while the timing problem would be solved in the modifications of the engine cycle. In a series of articles soon to be published in THE AUTOMOBILE, we shall devote considerable space to this interesting subject.

Our Correspondent Must Judge for Himself.

Editor THE AUTOMOBILE:

[552.]—As a subscriber to your journal, I would like to ask a few questions. Would you advise the purchase of a car with six cylinders such as the Ford company makes, or would you choose a four-cylinder car in preference? I simply mentioned the Ford Company's name because they manufacture such a car, though I presume there are others as well. Also, do you think a two-speed planetary transmission is the proper thing for a six-cylinder car, or would you prefer the sliding or selective type? Can you give me a list of manufacturers who make six-cylinder motors to sell to automobile makers?
F. F. MILLER.

Akron, O.

There is as much difference of opinion as to the relative advantages of the six and four-cylinder types of cars as there is concerning what constitutes beauty in a woman, and, as you would have to depend on your own personal opinion in the latter case, so you will also in the former. Why not ask someone who has had experience with a six-cylinder car? Give him free rein, and let him tell you all about it; then go to someone else who has had sufficient experience with a standard make of four-cylinder car and do likewise. If you have the time and opportunity to repeat the process several times in each case, so much the better. You can then be safely guided by the preponderance of evidence on either side after you have balanced the accounts. As to the suitability of the planetary gear in such a situation, all

we can say is that the design in question is that of a well-known engineer; it was not adopted haphazard, but only after thorough trial, and, as after a year's experience with it on a number of cars, he has seen fit to continue it unaltered this year, there appears to be no reason to doubt its efficiency. We may add that it is a more "foolproof" type than the others. We cannot help you out on the last question; probably some of our advertisers in that line may be able to do so.

An Interesting Case of Responsibility.

Editor THE AUTOMOBILE:

[553.]—The "Literary Digest" of January 12, in a series of interesting items relative to automobile accidents, contains the following excerpt from a recent issue of "The Automobile":

"An agent's driver left a car this way at the curb facing one belonging to another agent, and which stood about fifty feet away. One of the usual type of hangers-on about the garage began to monkey with the side levers, and before he realized what he had done the car started off at a good pace down the avenue. It brought up against the second car with a crash, and the resulting damage led to legal proceedings in which the plaintiff was worsted, owing to the non-liability of the defendant for the acts of the irresponsible person who was the moving cause of the damage."

The case referred to appears to be analogous to a case that I have at present in the courts here, and I shall be very glad if you can give me the title of the case, and the name of the court in which the same was determined. The "Literary Digest" does not give the date of the publication from which the quotation is made, but I trust that you can give me the desired information without putting yourselves to much trouble.

Denver, Col.

HENRY H. CLARK, Counsellor at Law.

The incident you refer to appeared in THE AUTOMOBILE, under the caption of "How Not to Leave a Car," as the accident in question was the result of leaving a car at the curb with the motor running and the gears in engagement, nothing but the emergency brake holding the clutch out. As the brake in question is operated by a side lever, its release is a natural result of tampering with the latter, and as this permits the clutch to engage, the car will start if the gears of the transmission are in mesh. The action lay between two of the Chicago representatives of leading manufacturers, and as the amount claimed was small, it was probably not brought in a court of record. We cannot cite the case, nor state the court it was brought in, nor can we say whether the matter was ever carried any higher.

Shock Absorbers as a Standard Equipment.

Editor THE AUTOMOBILE:

[554.]—There are numerous shock absorbers advertised in your magazine, claiming to be proof against the breakage of springs, etc. If this is so, why are they not generally adopted by the manufacturers of automobiles?

A SUBSCRIBER.

Sleepy Eye, Minn.

This is a question that only the manufacturers themselves can answer satisfactorily. Probably it is because the shock absorber originated as an accessory and still remains in that category; it has not yet reached the status of forming an integral part of the standard equipment of the average car. It may be added for your information that there are a number of manufacturers of well-known cars who have decided to fit their cars with shock absorbers regularly.

Putting a Condenser on a Small Steamer.

Editor THE AUTOMOBILE:

[555.]—I have a small steam runabout, and would like to know the practicability of putting in a condenser by dropping the exhaust to bottom of water tank through coil and place drip through tank to pump placed below, rising again with the exhaust to the open air.

Atlantic City, N. J.

JOHN W. TAYLOR.

There appears to be no reason why such an expedient should not prove successful, though it would seem that unless such a condenser can be built or purchased at a comparatively low cost, the benefit to be gained would hardly warrant the outlay. If possible the tank should be placed in such a position that the cooling water may be kept at as low a temperature as possible, as on this will depend the efficiency of the condenser.

Wants to Know About Self-Starting Devices.

Editor THE AUTOMOBILE:

[556.]—If, to your knowledge, there is no motor starter in existence, is there any desired by the manufacturers, and would you consider an invention of any great value, that would successfully start gasoline automobile and stationary engines from a standstill, dispensing with batteries entirely and using a small dynamo to furnish spark after engine is started?

Columbus, O.

FRANK FINSTERWALD.

There are quite a number of self-starting devices on the market for starting both automobile and stationary gasoline engines, and have been for several years. Various means are employed, such as springs, compressed air, gasoline and air, acetylene gas and air, carbonic acid gas and others. In spite of this, however, there would undoubtedly be a considerable demand for a device that was an improvement over any of the foregoing. None of those mentioned have met with any very general adoption, except for starting stationary engines.

Agricultural Implements That Are Motor-Driven.

Editor THE AUTOMOBILE:

[557.]—Will you kindly advise me if there is made in this country a machine used for agricultural purposes, such as plowing and heavy hauling? I understand that there is such a machine used quite extensively in England, and would like to know who makes them, as we have had applications for two of them.

Zanesville, O.

CHAS. E. FIX AUTO. COMPANY.

So far as we are aware, there is no such machine made in this country, using gasoline as a motive power, though portable gasoline engines are employed for agricultural work to the extent of many thousands. The English machines you refer to are made by Ivel Motors, Ltd. We understand that the International Harvester Company, Chicago, Ill., has been experimenting along the same lines, and as they are probably the largest builders of agricultural machinery in the world, can doubtless give you the information desired.

Roller Contact and Wipe Contact in Commutators.

Editor THE AUTOMOBILE:

[558.]—What are the respective advantages and disadvantages of the roller contact and the wipe contact in the modern commutator?

Watertown, Wis.

M. H. GAEBLER.

Generally speaking, wear is the greatest disadvantage of the wipe type of contact maker, though this refers more to the old time form of wipe contact maker, as numerous improvements have been made which have overcome this to a very great degree. The chief disadvantage of the roller type is the difficulty of making an adequate electrical contact, though no unusual amount of trouble appears to result from this cause in the modern timers of this class. The ideal timer is one that combines the efficient contact of the old time wipe type with the minimum wear of the roller or ball type.

THE FIELD FOR RESILIENT WHEELS.

Editor THE AUTOMOBILE:

[559.]—In conversation with Thomas L. White just previous to the Madison Square Garden show, he strongly insisted that the broad field for a resilient, but not pneumatic, wheel is a wheel for commercial purposes. It was made impressively manifest to the writer during the Garden week, by leading engineers of prominent builders, also, that the commercial field is a very broad and continually expanding one and well worth cultivating, but the query immediately presents itself to the inventive mind: What is the consensus of opinion of both manufacturers and users combined, as to what device will meet all the requirements? One engineer prominently connected decisively adhered to the opinion that any resilient wheel, rubber covered to give traction, would meet popular favor, yet in less than one hour another, equally as prominent, determinedly insisted that any form of wheel for commercial use having rubber as a component part is not to be considered for permanent and economical adoption. Which was right? It is such diversity of opinions as quoted that places the progressive inventor between the devil of doubt and the deep sea of uncertainty. Having patented a resilient but not pneumatic wheel for pleasure pur-

poses which has met public approval, as manifested by orders received during show week, and which was illustrated and described in the October 26 issue of "The Automobile," it intuitively presents itself as a reasonable proposition and conclusion that a wheel can be produced in the immediate future that will conform to any and all intelligent demands, when it is once made known exactly what is required. The extreme variations of weight of load to be carried is a complex and difficult problem, for it is assumed that a truck may leave the warehouse or shipping room with one load weighing, say, five tons, and the succeeding load may weigh less than one ton, but sufficient resiliency must be maintained under these widely divergent approximate loads to give satisfactory results and meet public approval. Probably no pneumatic or solid tire has been produced that gives equal resiliency under such varying loads, and while it may be possible, yet it appears wholly improbable that such a device will make its appearance. A wheel to be equally resilient in conveying the maximum and minimum load over every conceivable construction of road must of necessity be provided with a compensating appliance which will adapt itself to constantly varying conditions.

This communication will have met its express purpose if it produces definite information from intelligent and progressive founts of knowledge through the columns of "The Automobile" or otherwise.

H. S. PULLMAN.

Meriden, Conn.

FROM AN ADMIRER OF THE "HORSELESS AGE."

Editor THE AUTOMOBILE:

[560.]—The venom of your attack upon the editor of the "Horseless Age," in your issue of January 10, rather suggests that it was provoked by the sting of truth. In commenting on your editorial, I should like to point out that the fact that a certain article will "sell" is not, of itself, a conclusive argument in its favor, except from the point of view of those who market the article. Opium, indecent literature, and many other undesirable commodities would, if permitted, command large sales. Similarly, children, if at liberty to do so, would maintain a flourishing market for all sorts of improper playthings, which would be a menace and nuisance to everybody else. This is about the situation with the high-powered runabout, except that those who buy them are, on account of their years, not supposed to be children.

I am not saying that the high-powered runabout is, in itself, a menace and a nuisance, as it can be and often is handled with as much temperance as the high-powered touring car. But the fact remains that a 50 or 60-horsepower car, costing from four to five thousand dollars and capable of accommodating only two, or at most three, persons, is not a sensible, legitimate, or sane form of vehicle and, in general, appeals only to the class of individuals who want to "cut a dash" with a car that is racy and sporty in appearance and who want to gratify their own ambitions with a machine that will give them the greatest speed for their money. "Greatest speed for the money" is the only real excuse for the high-powered runabout, and were it not for speed maniacs and cheap sports, sales of this type would cut a small figure.

It is therefore the nature of the demand this vehicle caters to, and not the vehicle itself, that causes sober-minded automobilists to disapprove of the present fad in these "hell wagons," as they are so aptly termed. It is not a healthy demand and, therefore, the makers are short-sighted in booming it as they are. As the fad is in full swing, however, the best way to get rid of it is to let it run itself into the ground. When the high-powered runabout is no longer "swell," it will not be extinct, nobody wants it to be, but it will receive only the attention it deserves.

As to your arguments on the alleged merits of this type, they are a sham and you know it. They may apply to the runabout construction, but that does not justify the retelling on a wholesale basis of road racing machines to be used more or less as such on the roads and streets every day of the week and perhaps twice on Sunday. Also it may not have occurred to you that the seats of a runabout are no more between the two axles than are the front seats of a touring car. Furthermore, the weight of a tonneau, which is not "several hundred pounds," in the sense in which it is apt to be understood, is inconsiderable to a car of 60-horsepower.

And don't you worry about the editor of the "Horseless Age." He and his paper are all right and have the right idea on this question, as on racing and every other question they have ever tackled. The paper is made up of news and unbiased and intelligent comment, and is not guided in its policy by any interest in the "selfish point of view of those who market the article." I am not influenced in this letter by any partiality, as I am not personally acquainted with the editor of the "Horseless Age," and do not read his paper any more than I do some of the other automobile journals. That I am not personally acquainted with him, however, will not prevent me from sending him a copy of this letter.

Cambridge, Mass.

DEMAREST LLOYD.

CURRENT CONSUMPTION AGAIN CONSIDERED.

Editor THE AUTOMOBILE:

[561.]—I read with a good deal of interest C. T. Jones' letter on Current Consumption (543), as it seems to bring up a good many interesting points. As a matter of fact, the current required to properly spark an engine for a given time increases in direct proportion as the speed increases. On the other hand, with the ordinary forms of timer and vibrating coils the amount of current consumed by an engine while running a given time will be practically the same no matter at what speed the engine be run.

In some special forms of timers, such as the Atwater-Kent, in which the time of contact per spark generated is the same, regardless of the engine speed, the current consumption increases in direct proportion to the speed of the motor. However, in certain instances the current consumption may actually decrease to a slight extent as the speed of the motor increases.

To illustrate, before the core of a coil is sufficiently magnetized, so that, when a break in the primary circuit is made, a sufficiently strong spark will be created at the plug, the current must pass in the primary for a certain time. This amount of time depends on the construction of the coil and upon the voltage of the current used. Furthermore, the magnetic inertia of the core tends to resist the flow of current in the primary so that the amperage of the current flowing in the primary will gradually increase as the coil becomes magnetized. The time required for the current flow to reach its maximum is somewhere between one one-hundredth and one one-thousandth of a second. Let us now suppose that the primary circuit is broken just as the amperage reaches the maximum, then the average current flow will probably be somewhere near one-half the maximum flow. However, let us suppose that the circuit is not broken until a short time after the current has reached its maximum, then the average amperage of the current flowing will be considerably raised. Let us now apply this reasoning to the case of a non-vibrator coil and the form of circuit breaker that is commonly used on a motorcycle. Let us suppose that the time of contact is so adjusted as to be just sufficient to form a good spark at a given speed. Let us now slow the motor down to one-half that speed. Then the number of contacts in a given time will be decreased just one-half, but the duration of each of these contacts will be doubled so that the total time of contact will remain the same whether the motor runs fast or slow. However, as has been shown, the average current flow has been raised, therefore the total current consumption has been raised by slowing down the motor.

In case a vibrator coil is used, then the situation will become slightly more complicated; however it is practically true in both cases that, with ordinary timers, the consumption of current is the same for a given time, regardless of the speed of the motor. The waste of current at the slower speeds of a motor is something surprising.

Let us say that a motor capable of turning up to 1,200 r.p.m. has a commutator designed for just sufficient contact to give a spark at this speed. Let us suppose that the motor is slowed down to, let us say 400 R.P.M., in this latter case three times the current is being used as is actually needed. Formerly some of the Columbia cars were fitted with a timer in the design of which cognizance was taken of this fact, it being so designed that as the spark was advanced the arc of contact was increased, the idea being that spark advance generally meant increased speed.

Mr. Jones also makes the very common mistake of confounding battery life with current consumption. A dry battery will give a much greater number of ampere hours' output if the work is of an intermittent nature than if it is more continuous. Both dry and storage batteries tend to give a greater ampere hour output if the discharge rate is kept fairly low. It is probable, therefore, that battery consumption is slightly greater at high speeds than at low in the case of dry batteries, but that with storage batteries there is little or no difference at high or low speeds under ordinary conditions.

HAROLD H. BROWN.

Boston, Mass.

GERMAN MOTORS OFFICIALLY RATED.

The rating of internal combustion motors has been made the subject of an Imperial Treasury investigation in Germany, and as a result automobile motors are now to be rated by the formula, N equals $0.3 id^2s$, in which N is the horsepower, i the number of cylinders, d the diameter of the cylinder, and s the stroke, the quantities being expressed in metric terms. The formula is based on a speed of 900 r. p. m. and a mean pressure of 3.8 kilogrammes per square centimeter. This official formula of the German Government used for levying the horsepower tax has also been adopted by the Automobile Association of Central Europe.

OPERATING SIDE VIEW OF MODEL 25, RAMBLER TOURING CAR, 35-40 HORSEPOWER.

FOR the present year the Rambler line will consist of a double opposed runabout, known as Model 17; a utility car with double-opposed motor, designated as Model 21, and two touring cars with four-cylinder vertical motors, classed as Models 24 and 25. These two latter models are the most important of the Rambler line, and, while similar in general character to Models 14 and 15 of 1906 which they replace, show marked improvements in every essential feature over their predecessors. Model 25 is a large touring car with 112-inch wheelbase and standard tread, while Model 24 is a medium-weight touring car with many new, but thoroughly-tested features.

The four-cylinder motor of Model 24, developing 25-30 horsepower, has separate cylinders 4 1-2-inch bore by 4 1-2-inch stroke, cast with integral heads. The valves, which are assembled in separate cages and securely seated in the dome of the combustion chamber, are operated by rocker arms provided with adjusting screws, whereby the time and extent of opening is accurately regulated. The hardened valve cams are made in integral pairs for each cylinder, one adjustment thereby assuring the action of inlet and exhaust valves in proper relation to each other. The lift rods act through long bronze bearings provided with hardened steel rollers to prevent wear through contact with the cams. Inlet valves being set above the combustion chamber allow room for the spark plugs directly under the valves. By this means the plugs are always cool and clean. Four rings are provided on each piston, three being above and one below the

piston pin. Pistons and rings are given a mirror polish. Probably the most notable feature of this motor lies in the construction of the crank case and method of support. Instead of being divided horizontally at the center line of the crank case, the body of the case is built solid with a removable plate at the cam side. This plate covers the entire side of the case, extending downward from the top nearly to the bottom, leaving only a reservoir of oil. By removing this plate, the entire crank shaft, with all its bearings, as well as the cam shaft, is entirely exposed. The main bearings are three in number, of ample size, and of a special anti-friction metal that has such great wearing qualities that adjustment is unnecessary, even after a season's hard service. Three-point suspension is employed for the motor with a universal joint between clutch and transmission gear. At the forward end of the crank case is a sleeve, through which passes a steel

tube extending across the frame, the ends supported in trunnion blocks secured to the frame sides. At the rear of the case is a segmental bearing resting on a depending cross frame member.

Ignition.—Jump spark ignition is employed, the system comprising a six-volt, sixty-ampere storage battery, a four-unit coil located on the dash, and a roller-type commutator of special design. A leading feature is that the member to which the wires are attached is stationary, even when shifting the spark, thus avoiding breakage of wires and connections. After exhaustive tests the roller contact system has been adopted for all 1907 models. By the use of tool steel rollers and contact plates wear

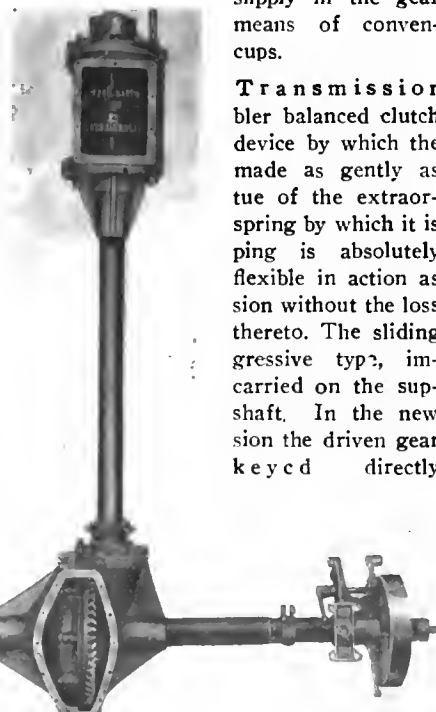

MOTOR OF MODEL 25, VALVE-OPERATING SIDE.

is almost eliminated, and absolutely correct synchronizing of ignition is attained.

Carbureter.—A new type of carbureter with automatic air control is now used. The gasoline feed is regulated by a float, with the nozzle concentric with the float, thereby removing all trouble incident to throwing the carbureter out of vertical alignment, as in running on a slanting road or steep grades. Air control is by three automatic valves with springs of varying strength. By this construction more accurate air adjustment is assured at different engine speeds than could be attained by varying compression of a single spring. Throttle control is by means of a butterfly valve in the inlet pipe to the motor. The gasoline tank is placed under the front seat, and is reached for filling by removal of the operator's cushion. Its capacity is fifteen gallons.

Lubrication.—The belt-driven, mechanical, force-feed oiler delivers measured quantities of lubricating oil to every point of friction. Parts other than those supplied by this oiler are, except the transmission gears, which supply in the gear means of conveniently located grease

Clutch and Gears.—The Rambler is an entirely new engagement may be desired, but by viridinary powerful finally seated, slip-eliminated. It is as a friction transmission of power incident gear is of the promersed in oil, and part of the propeller Rambler transmission one shaft is not

REAR AXLE AND TRANSMISSION, MODEL 24.

thereto, but is seated on the hub of a driving arm. This driving arm projects through the web of the driven gear with a play of about ten degrees, and allows the gear to yield slightly and permit easy engagement of the shifting gears. The arm is normally centrally balanced by springs projecting from each side and bearing against the shoulders, but when the car is in motion bears solidly against those shoulders in the direction of rotation. The propeller shaft bearings consist of two adjustable roller and one cylindrical bearing. The rear axle is of the floating type, with ball bearings at the inner ends and roller bearings in the wheels. The driving axles are of extra large construction with the spur gears of the differential forged on the inner ends. This construction eliminates the trouble unavoidable in separate gears, whether keyed or otherwise. Hand plates are provided in both transmission and differential gear housings, enabling adjustments to be easily made.

Cooling.—The Rambler engines are water-cooled, circulation being assured by means of a centrifugal pump located on the camshaft. A flat tube radiator is employed, with five-blade fan driven by belt direct from the motor shaft.

MODEL 25 MOTOR, INLET AND EXHAUST SIDE.

Control.—Motor control is effected by the familiar Rambler ring throttle under the steering wheel used in connection with separate levers for spark and auxiliary air control.

Wheels and Brakes.—Road wheels are wood artillery type, 34 inches in diameter, with 4-inch tires. Standard tire equipment is Hartford-Dunlop, but G & J, or Diamond, are optional. Two sets of brakes are provided, both acting upon drums, in the rear hubs. Primary brakes are applied by pedals; the emergency brakes, of expanding ring type, acting upon brake-drums of each rear wheel, are operated by side lever.

Model 25 is altogether of heavier construction than Model 24. The four-cylinder engine is 5 inches bore by 5 1-2 inches stroke, developing 35-40 horsepower. Change-speed gear is also of the sliding type, giving three forward speeds and reverse, with gears of large diameter, but the final drive is by chain to each rear wheel; the differential gear is enclosed in the case with the sliding gears. The transverse shaft carrying the driving sprockets rotates within tubular sleeves extending outwardly from the gear case and suspended from the side frames by drop-forged supporting blocks.

Bodies.—Both Models 24 and 25 carry handsome, well-finished side entrance bodies, upholstered in the best style, heavily padded with curled hair over ample springs. Model 24 is finished in pearl gray with buff leather; Model 25, beechnut brown with darker trimmings and gold striping, upholstery in black leather. Equipment comprises full cape top with storm aprons, gas headlights, oil side and tail lights, horn, pump, full set of wrenches and tire-repair kit. The catalogue price, thus equipped, is \$2,000 for Model 24 and \$2,500 for Model 25.

TRANSMISSION OF MODEL 25, WITH COVER REMOVED.

Model 21, known as the utility car, differs in many respects from the two just described. Its power plant consists of a double-opposed engine with cylinders 5-inch bore by 6-inch stroke, carried under the body. The transmission gear is the planetary type located on an extension of the motor shaft and entirely enclosed. The gear case is attached directly to the crank case, and contains the change-speed gear, fly wheel and multiple disk clutch. An integral unit is thus formed, with three-point suspension, and of such strength and rigidity that no torsion of the motor frame can cause disalignment of the gears or bearings. Final drive is by single chain to rear live axle. Ignition is by jump spark; lubrication is by pressure feed with three sight-feed regulators on the dash, oil being carried from these to both cylinders and to the gear case. The engine is water-cooled, circulation being by thermo siphon, with a flat-tube radiator giving about 10,000 square inches of cooling surface. Lack of accessibility has often been urged against horizontal motors carried under the body. In the Rambler no such difficulty is known; every part is perfectly accessible. The body of the car is absolutely independent of all controlling mechanism and is secured to the chassis by means of two lock hinges on each side of the body and outside the frame. By loosening a hand-nut on two of the locks the entire body may be swung to the opposite side and held there by braces; or, by loosening all four hinges, the body may be entirely removed in less time than is usually required for taking out the floor boards.

Convertible Body.—A strictly new design of the convertible type has been adopted for Model 21. The front seat is divided and the tonneau is very roomy with wide doors opening forward. Used as a two-passenger car, the tonneau is replaced by a torpedo deck, or, if an extended tour is contemplated, the deck may be omitted and the floor used for hampers, camping kit, etc. The suspension is by semi-elliptic front springs and full elliptic rear springs with involute ends and double shackles. Wheels are wood artillery type, 30 inches diameter, with Dunlop universal rims and 4-inch tires. Upholstering and finish are of the highest grade. The standard color is an occidental red-brown, with dark-brown trimmings, striped with a narrow gold line. Upholstering is a red that harmonizes with the body color, and all metal trimmings are highly-polished brass. Equipment comprises two headlights, oil side and tail lights, horn, wrenches, oilers, pump and tire-repair outfit. Price, with tonneau, is \$1,350; with torpedo deck, without tonneau, \$1,250.

Model 17, a runabout with double-opposed engine carried under the body, is the smallest of the Rambler cars, and was fully described in our issue of September 20.

RARITAN BRIDGE TO BE CLOSED AGAIN.

PERTH AMBOY, N. J., Jan. 28.—The new bridge across the Raritan river at Perth Amboy, recently opened to the public, will be closed for three months this spring by order of the War Department, and New York automobilists who have been reaching the New Jersey coast resorts by a route leading over this structure will have to resume the old route, by way of New Brunswick.

Three of the spans of the new bridge will have to be torn out and replaced with spans of steel, in order to have the structure comply with the department regulations. The department contends that the bridge, as it is now, is an obstruction to navigation. It has been decided to close the bridge to traffic on March 1. The old route, leading through Newark, Elizabeth and New Brunswick, makes the trip from the metropolis to the seashore towns about thirty miles longer than by the new way.

New Castle county, Delaware, has asked the legislature to permit it to borrow \$200,000 with which to build substantial permanent roads within its borders.

NEW YORK-BOSTON AUTO SPEEDWAY.

BOSTON, Jan. 28.—Among the petitions for new Legislation filed at the State House just before the time for filing new bills expired, was one drafted by James F. Bacon, a Boston lawyer, which asks permission to incorporate the "New York and Boston Automobile Boulevard," for the use of automobiles, motor cars and general transportation purposes. The proposed capital of the company is \$2,500,000, and it is desired that the route of the boulevard shall be as nearly as possible an air line touching the following Massachusetts towns and cities: Newton, Brookline, Needham, Dedham, Dover, Medfield, Sherburne, Millis, Medway, Bellingham, Milford, Mendon, Blackstone, Uxbridge, Douglas and Northbridge.

This scheme is supposed to be a part of the general plan for a through line, and the route probably will connect with that proposed by a similar company to be organized in Connecticut, and which will petition the Legislature in that State for similar privileges. It is understood that the promoters of the scheme desire in effect two broad roadways, one for cars going east and the other for cars going west. It will be a toll road, with fees for its use, and entrances every few miles its entire length. The provision in the Massachusetts bill under which the road may be used for "general transportation purposes" is looked upon with some suspicion, as it is feared that under that clause the company might acquire a valuable right of way and use it for a railroad.

Charter Also Applied for in Connecticut.

HARTFORD, CONN., Jan. 28.—Notice of an intention to file a petition to the general assembly of this State for permission to construct an automobile speedway across the State of Connecticut has been filed with the Secretary of State. The signers of the notice are Col. George Pope, A. L. Pope, W. C. Walker, and Charles E. Walker, of the Pope Manufacturing Company, of Hartford, and E. L. Ropkins, of Hartford. The incorporation which will present this petition is to be known as the Connecticut Automobile Parkway Corporation.

When seen by a representative of THE AUTOMOBILE, Col. Pope stated that the proposed incorporators do not contemplate anything but the construction of an automobile speedway. Politicians are inclined to believe that the proposed corporation intends to secure a charter and then lay trolley or railroad tracks side of the auto speedway in competition to the New Haven road, which has long enjoyed a monopoly in the State. Col. Pope states that the corporation will be nominally capitalized at \$100,000. If a charter is secured, work on the path will be started next spring or summer, but it will take several years to complete it.

It is proposed to connect New York and Boston, and the route for the most part will be by private right of way. It is also proposed to run cars at a faster speed than the laws permit on public highways, and to charge tolls to pay interest on the investment and maintain the route. The petition also asks for authority to exercise the right of eminent domain, which gives it the right to condemn and take private land for the construction of the proposed parkway.

SIXTY-MILE AUTO HIGHWAY PROPOSED.

Joining the Bronx concourse and the proposed Catskill Aqueduct automobile highway, so as to make a continuous boulevard sixty miles long from Manhattan borough, New York City, through the Bronx to the Hudson river near Poughkeepsie, is now being discussed by residents of the Bronx. The highway for automobilists would start from the Hillview reservoir, and the concourse, for all vehicles, which is to run from Central Bridge to Mosholu Parkway, could easily be connected with the suburban motor highway. The president of Bronx borough, Louis F. Haffen, is greatly interested in the movement to connect the two systems, and is advocating the plan in conjunction with a number of leading citizens.

ONE of the latest additions to the ranks of popular-priced cars, for which the demand is so large, hails from the middle west. It is called the Kisselkar, and its home is at Hartford, Wis., thus adding another to the growing list of western towns that include automobile manufacturing among their industries. It made its debut at the opening of the year and, unless the plans of its sponsors miscarry, it should prove a factor in the trade before the season is well under way. Instead of attempting to place something of a revolutionary nature on the market, its builders have profited by the combined experience of the many designers who have preceded them and have taken heed to avoid the latter's mistakes, so that far from being something in the nature of an "inventor's pet," the newcomer represents as close an approach as possible to what is regarded as standard engineering practice for cars of this size.

Motor.—This follows universal practice in that it is of the four-cylinder vertical type, designed to be placed forward on the chassis under the bonnet. The cylinders are cast in pairs with the waterjackets integral, both the intake and exhaust valves being grouped on the same side. The direct or push-rod type of operation is employed, both valves being mechanically operated and both being interchangeable, beside being very accessible for removal in case of repair. The valves have been given a liberal diameter, thus permitting of a short lift which makes for a highly efficient engine at all speeds, as it insures rapid filling and emptying of the combustion chamber, as well as a very silent-running engine. The connecting rods are drop forgings of high-grade steel, both the big end bearings and the main bearings being of Parson's white bronze, which is very highly regarded for automobile engine work. The single camshaft is completely inclosed and lubricated from the inside in accordance with the latest trend of design in this respect.

Lubrication.—This essential is well provided for in the shape of a mechanical force-feed oiler driven from the motor and with a number of different leads, feeding directly

to the lower edges of the pistons in each cylinder and the front and rear main bearings, the surplus draining into the crankcase, where a constant level is maintained to provide for splash lubrication. Partitions are provided in the crankcase to prevent flooding either end of it with oil when traveling up or down grades. The crankcase is divided horizontally, the lower half being merely an oil pan or reservoir, so that its removal renders all the moving parts of the motor readily accessible with very little trouble. Considerable attention has been given to this where every part of the motor is concerned so that inspection and removal of parts is made easy. The motor is designed to run at speeds varying within a wide range, but develops its normal rating of 30 horsepower at 1,200 r. p. m., at which it is very quiet in operation.

Carbureter.—This is of the well-known Schebler make, with vertical air inlet, and is placed on the left-hand side of the motor quite low down, the inlet manifold being horizontal and fastened directly to the cylinders at the level of the inlet valves. It terminates in a perpendicular downward pointing outlet which is coupled to a special offset with a flanged coupling, bringing the carbureter almost down to the level of the dividing line of the crankcase. The cold water inlet of the circulating system is placed immediately beneath the inlet manifold, so that, as the photo of this side of the motor shows, all the piping necessary is confined to a very small space and is very accessible. The hot water outlet

from the jackets rises from the center of the top of each pair of cylinders, circulation being maintained by means of a gear-driven pump.

Ignition.—The high-tension system of ignition is employed, a set of accumulators being used as the source of current supply. The timer is mounted on a vertical shaft bevel gear-driven from the camshaft. It is placed at the rear of the motor, and is about on a level with the highest portions of the motor, thus making it very accessible and reducing the amount of wire necessary for primary connections. The plugs are situated over the inlet

HOW THE WORKING SIDE OF KISSELKAR MOTOR LOOKS.

THE FRONT AXLE OF THE KISSELKAR COMPLETE.

valves, which brings them close together on each pair of cylinders and also serves to reduce the amount of wiring necessary on the secondary side of the ignition system.

Transmission.—The change-speed gear is of the sliding type, providing three speeds forward and reverse, the method of operation being the selective, which has met with unusual favor at the hands of designers during the past year or so and is now a feature of a great many cars of all powers. The gears have been designed with very large faces, the teeth being cut so as to permit of a very easy entrance, thus avoiding clashing. They are made of high grade steel, specially hardened and ground to size. Both shafts of the change speed gear run on Timken roller bearings. The rear axle is of the floating type, clutch driven, a spur gear differential being employed. This can be readily removed without the necessity of dismantling the axle, by simply removing the cap of the gear case, which exposes the entire differential and bevel driving gears to view. Timken roller bearings are used throughout this part of the car, two of large size being placed on the pinion shaft, with centers 5 1-2 inches apart, thus insuring absolute alignment at all times. As shown by the illustration of the rear axle driving unit, an unusually large torsion rod is used. It runs parallel with the propeller shaft, and is hung at its forward end immediately back of the change speed gear box, thus preventing any distortion of the propeller shaft. The latter is equipped with a large universal joint at its forward end, in order to prevent its binding from the twisting strains of the car caused by traveling over uneven roads.

Brakes.—As has come to be the almost universal trend of modern practice where this highly essential part of the car is concerned, both sets of brakes have been concentrated on the rear wheels. They are housed in a specially designed drum, the external brake, which is interconnected with the clutch, being operated by the pedal for ordinary running service, while the emergency brake is of the internal expanding type, and is also interconnected with the clutch, thus making it impossible to apply the brake in either case with the power of the motor still being transmitted to the driving wheels. By removing a single small bolt, either the running or the emergency brake may be readily disconnected from the clutch, allowing it to work entirely independent of the latter. In addition to the transmission and the rear axle Timken roller bearings are also employed in the front and rear wheels. A liberal size bearing has been provided in every instance, so that the makers fully

REAR AXLE SHOWING ITS KINDRED APPLIANCES.

guarantee them for two years, and will replace them with new ones should they break or wear out within that time. The foundation of the chassis consists of the standard type of channel section pressed steel frame, the axles being spaced to give a 98-inch wheelbase, the running gear consisting of 32-inch wheels shod with 4-inch tires. The Marsh quick-detachable rim is furnished as a part of the standard equipment, this rim permitting of the employment of the Diamond quick-detachable tire or any standard make of clincher tire. With the usual touring body the car comfortably seats five people, and when equipped with side lamps, horn, set of tools, storage battery, tire repair outfit and pump, it lists at \$1,850. The car can also be bought with complete equipment, consisting of a side arm Pantasote top, acetylene headlights, Prest-O-Lite tank, tail lamp and Warner speedometer, with which it lists at \$2,100.

A ROUTE TO THE JAMESTOWN EXPOSITION.

"White Route Book No. 2," just issued by the touring bureau of the White Company, New York, covers a wide sweep of country that is just now receiving a great deal of attention from automobile tourists. In brief, it gives the most popular—and, in fact, the only practicable—pleasure route for automobiles between the Northern cities and the Jamestown Exposition. The running directions in Route Book No. 2 start from New York across Staten Island, and take the usual route from Perth Amboy to Trenton and Philadelphia. Two practicable routes are outlined from Philadelphia to Gettysburg; one via Lancaster and York, the other via Lancaster, Mount Joy and Harrisburg, these two coming together at Gettysburg.

From this point the run is made from Gettysburg through Waynesboro, Pa., to Hagerstown, Md., and Winchester, Va. Here the route through the famous Shenandoah Valley is taken up and followed to Staunton, where the Valley Road is left for a nearly direct line south-and-east across Virginia, through Charlottesville, Richmond and Petersburg, to Norfolk.

From Hagerstown through the Shenandoah Valley, and all the way to Norfolk, this route is identical so far as the country covered and the points passed through are concerned, with the corresponding trip made by Augustus Post last summer, under the auspices of the Jamestown Exposition authorities and the auspices of the Richmond Automobile Club.

The style of compilation in the two routes varies somewhat, but the White booklet has the advantage of various small photographs, illustrating the important points along the route; it also has a general map, which gives an excellent idea of the route all the way from New York and Philadelphia to the end. It is an enterprising piece of work, and deserves the wide circulation that will undoubtedly be had for it.

PROSPECTS OF THE PENNA. STATE HIGHWAY.

PHILADELPHIA, Jan. 28.—The many advocates of a trans-state highway among the automobiling element here were somewhat taken aback at the announcement that State Senator Blewitt, of Lackawanna county, would introduce a resolution in the Legislature asking for a survey by the State Department of Highways of a route for a 32-foot-wide macadam boulevard from Easton to Pittsburg via Sunbury, with branches to Scranton and this city. They greatly fear that the division of sentiment between that route and the one generally accepted—via Lancaster, Gettysburg, Bedford, Greensburg, etc.—may result in a knockout for both. The latter, besides being the shorter, has fewer physical difficulties in its way, and could be constructed for considerably less money. Certain it is that the solons now in session at Harrisburg will not listen to a double route across the State, and there is reason to fear that the legislators will adopt the usual compromise of killing both as a sure method of side-stepping possible antagonism. Under the circumstances the prospects for the highway are far from encouraging at the present session.

BY
FRANCIS MILTOUN

(Continued from last week.)

SO much for the hotels of the large towns: they can't give you for a moment anything like the good cheer and the good feelings which possess you after you have been a guest of the Hôtel de la Poste at Tournon, the Hôtel de France at St. Girons in the Haute Pyrenées, the Hôtel Lieutaud Cassis in the Var, or the Hôtel du Bon Laboureur at Chateaudun, where at any or all of these you are launched at once in the midst of a locally characteristic atmosphere with the *patron-chef* cooking your dinner for you and his buxom wife running the cash box in that strictly personal way which forms one of the great and intimate charms of French travel.

It is in such hotels as these that one gets a genuine warm welcome and a hearty hand-shake on leaving, the personnel meanwhile not hanging about cadging for sous, even though the *bonne* has brought you innumerable jugs of *eau chaude*, and the *marmiton* and *garçon-de-remise* has fussed around with you and the machine while you were filling up with essence, oil and water. No, you give what you like, four sous here, fifty centimes there, and five sous there, and everybody satisfied.

It is in such hotels as these that one finds a mixed company of petty bourgeois, good, honest and simple folk all, and very exacting nevertheless with regard to their food and its cooking. When madame puts her head through the door of the café and says, "Allons, messieurs, à table," you file in and take your places ensemble; an army officer or two, perhaps an abbé, a local lawyer and his client, and three or four *commis-voyageurs*; very, very seldom any women folk.

Just recall the succulent *soupe aux choux*, the delicious *friture* (the little fish from the river just before the door), the inevitable *ragout* of something or other—wasn't it good? and the *rôti*, a duckling perhaps or a *pintard*, with a crisp salad with just a suspicion of garlic in the dressing (sometimes a trifle more), and a dish of *petits pois au naturel* (not the green, coppery kind specially put up for the English and American markets). Then there was the wine, a *vin de l'ouray*, perhaps, if in Touraine, or a *vin de St. Peray*, if on the banks of the Rhône; just ordinary *vin de table*, but *il n'était pas mal*.

A pointer, then, for stranger tourists en automobile in France: stop at some small town for déjeuner, or dinner, and the night instead of in the large towns, and get a taste of the real *cuisine du pays*, a rare, succulent thing which knows not "Liebig," aluminum and electric cooking utensils, or unpronounceable Russian names for the plats; stop at Tournon instead of Lyons, at Cassis instead of Toulon, at Blaye instead of Bordeaux, and at Les Andelys instead of Rouen.

The same thing applies all over France. Pick your hotel from the Guide-Michelin or the Annuaire of the Touring Club de France or the Automobile Club de France, and not from Baedeker or Murray. Another thing, if you travel with Baedeker as a guide, supplement it with Joanne, in French. Even if you don't read French it will be of untold value from an automobilist's point of view. For proof of this just compare Joanne's Normandie with Baedeker's Northern France and see what you gain with the former as to maps and plans and hints on the serious business of travel in that delectable province of old France.

A frowsy little hotel off the beaten track, with nothing of the Ritz-cum-Carleton about it, will leave a far better memory of its simple characteristic fare than the imitation Escoffier and Brillat-Savarin *plats* of the de luxe hotels, which in France, even, are the same dishes as in de luxe hotels elsewhere.

As for hotel prices, the whole continent of Europe is much cheaper, and the fare is much better, than one gets in England. It is not snobbery to decry the English resorts and say how much one prefers Ostend to Brighton, St. Jean-de-luz to Bournemouth, or Marienbad to Buxton; there is a difference—a wide difference—which need not be specialized.

It is by the mark to abuse English cookery; the grill is one of the sanest and most healthful forms of cookery extant, and the roast beef in England is proverbially good—when it is roast beef and not baked meat, and when it is not horribly hacked and butchered in the serving. All the same the hotel meals of England, even in the best of the resorts, are dreary, sad affairs with impossibly cooked French *plats* and a generous sprinkling of plain boiled as well. To take one item alone, a roast chicken, it is only in France that one can get a decent *poulet rôti*.

One thing to bear in mind, however, that the "resort" hotels the world over are perforce expensive and do not differ greatly—so far as the premier establishments go—and whether one is in the Engadine or on the Cote d'Azur, the Cote d'Argent, or the the Cote d'Emeraud: the final tinge is golden and of a rich hue. Closely allied with the hotel which caters for the wants of the automobile traveler are the establishments which can render a service to one's automobile as well—the repair man or *mécanicien*, as the Frenchman knows him.

The garage accommodations of the hotels themselves, the

ONE FINDS THE MECHANICIAN ALL OVER FRANCE.

LES ANDELYS

CHAMPTOCEAUX

ORLEANS.

THREE KINDS OF HOTEL GARAGES IN FRANCE.

actual storage places for your automobile for the night, are nearly everywhere all sufficient, and in some cases palatial, as at the Hotel de l'Univers at Tours, the Grand Monarque at Chartres, or in most of the large towns, such as Arles, Nimes or Avignon, at Remis, Bourges or Rouen. In the smaller towns one very often has to house the machine in an old stable, perhaps sharing it with the hotel omnibus, but in almost every instance some special effort has been made towards furnishing proper accommodation, so far as freedom from danger and a safe, dry place for storing one's machine is concerned. This is a good deal and more than you get in England, and in France you furthermore pay nothing for this accommodation. Remarkable this, many will think, but a very astute and intelligent move on the part of the French hotel keeper who would cultivate a new clientèle rather than drive it away, as more than one hotel proprietor in England is doing to-day. One does not think it a fair proposition to be charged a shilling or eighteen pence for leaving his machine in the uncovered courtyard of a hotel while he and his three companions are spending a guinea on a lunch.

The repair man, or *mécanicien*, even with the best regulated automobile families, is a necessity at times, and at other times a great accommodation. Your carbureter may have to come down—for a good and sufficient reason which you know well enough—and you had much rather someone else would do the job than bother with it yourself. A drop of solder on the *flotteur* is all that is needed, but it's an hour's dirty work getting at it and putting it back in place again. This will probably cost you a franc and a half (say thirty cents), and is not dear at the price.

You may have stripped a thread on a bolt and it is desirable to have another to replace it immediately. Your French *mécanicien* sizes up the situation in a moment and sees that you have an English or an American machine—and the threads are not metric. He doesn't attempt to do a "gas-pipe job," as do most of his brethren in England, but takes the bolt out bodily and turns down, perhaps, a large French bolt to the proper size, with its nut and thread all made, puts it in place and off you go at a cost of—well, a mere nothing. If this procedure is not wholly practicable, he will even turn you a nut with a "Whitworth," a "Standard," or any other thread (and he will do it on an American lathe, too—which he calls a *tour*). This is an art. One thinks almost as great an art as that which accomplishes the multifarious operations of the watchmaker, and

it takes a fair bit of time, but it won't cost you over a dollar and probably not that. Yes, the *mécaniciens* of France are a rare race of workmen. This is another of the pleasures of touring in France.

American Automobiles on the Roads of France.

Nowadays one sees not a few American automobiles on the roads of France. In a journey of last summer from a little Breton fishing village to another unspoiled little town near Marseilles, a little Oldsmobile was met gliding gently along a great tree-bordered *route nationale* in the midst of the plain of La Beauce; and within half a day a fifty-horse Thomas, and on the road by the Rhône, below Valence, a Pope-Toledo, and again a Pierce. It is the Americans, of all stranger automobile tourists, who are most frequently seen in France.

It was unquestionably remarkable that four American automobiles should be seen in succession, on such a cross-country run as this, but such is the fact, and it is the more remarkable because for one whole day, while skirting the "Massif-Centrale" (that volcanic region around Le Puy and Clermont-Ferrand) and the mountains of the Vivarais, not a mechanically propelled vehicle of any kind was seen, except a motor-omnibus of Lyons manufacture being "tried out" as to its fitness of the work that it was intended to perform. They had chosen a likely spot for the trial, for it was on an eighteen kilometer "hill" just outside of Roanne in the Haute Loire.

That night we slept at Lyons, at the Hotel de l'Univers et de l'Automobilisme, and paid our bill the next morning with every content as to accommodations and price, though there was added to the bill ten per cent. in lieu of *pourboires*. This was a novelty and it seemed to work well. Everybody satisfied: clients, servants and proprietor. But it must have taken a lot of nerve for the proprietor to cut loose from established custom.

PHASES OF BUSY AUTOMOBILE CLUB LIFE

A. C. of California Urges Careful Observance of Law.

SAN FRANCISCO, Jan. 22.—As a sample of the sensible work the executive committee of the Automobile Club of California is doing to popularize automobiling in this State, and ward off restrictive legislation, the following letter, recently sent out to automobile dealers in the State, stands out pre-eminent. The letter is given in full, and is worth careful consideration:

"As you are aware, frequent automobile runs have been made between San Francisco and Los Angeles, with the view of establishing so-called 'records.' While these runs have sometimes been made by privately owned cars, they have always been instigated and managed by dealers, with a view to advertising some particular make of machine, and thus furthering personal interests only. You cannot be unmindful of the fact that almost any of the present makes of machines, and certainly all of the goodly number of the best of them, are capable of making the average speed necessary to equal any 'record' possible under highway conditions, such a 'record' being merely a matter of skillful operation coupled with a fair amount of good fortune against ordinary roadway troubles. Such runs prove nothing else.

"In thus attempting to further purely selfish ends, participants in these runs willfully violate the State law applying to the use of the highways by automobiles, endanger the lives and property of highway users in general, and bring discredit and odium upon all automobile owners and users. It was through the efforts of the officers of this club that our present highway law was passed, and it is therefore felt to be incumbent upon the club to attempt to enforce the spirit of the law at least, and with that object in view a letter has been addressed to the Boards of Supervisors and the District Attorneys of several of the counties of the State, a copy of which is enclosed for your complete information. No class can be more interested in the continuance of our present law, or one having no greater restrictive measures, than automobile dealers, as large sales of cars depend greatly upon the purchasers' ability to freely use them without too restrictive conditions, and it would therefore seem dealers should be first and foremost in advocating the legal and rational, and not criminal, use of public thoroughfares."

As a general thing the public commends the club's action,

Spring Endurance Run Interests Central Penna. Autoists.

YORK, PA., Jan. 28.—At a meeting of the York County Automobile Association, held the other day, it was decided to purchase an individual tag to be placed on the cars. The tags will bear the inscription "York County Automobile Association," and the member's individual club number will appear on the tag below the above marking. The proposed State highway between Pittsburg and Philadelphia was also discussed by the members, and they are heartily in favor of such an improvement being made to the big auto road. Quite a few new members were admitted at the last meeting.

This city will be the chief checking station in the endurance run to be held April 8 and 9 by automobilists from this part of the State. The run will leave Harrisburg on the morning of April 8, and will proceed to Hummelst, Palmyra, and Annville to Lebanon, the first checking station. From Lebanon the cars proceed to Manheim, Lancaster, Marietta, Columbia, and then to this city. The night's stop will be made in York. The second day's run will take in Hanover, New Oxford, Gettysburg, Chambersburg, Shippensburg, Newville, Carlisle, Mechanicsburg, and thence to Harrisburg, where the final checking will be made. Two valuable trophy cups have been offered to the winners in the touring car and runabout classes. Many local tourists will

HOW THE CHICAGO AUTOMOBILE CLUB HOUSE LOOKED JANUARY 15.

The open winter has benefited the builders of the new palatial home of the Chicago Automobile Club, and the third story is now in progress. The illustration is from the official club "Journal."

compete in the run, and from present indications no less than twenty-five cars will be sent away from the Capital City on the morning of April 8, and probably twice that number.

Smoky City Autoists Plan a Busy Season.

PITTSBURG, PA., Jan. 28.—The Automobile Club of Pittsburg is taking on new life. Interest in the Pennsylvania Motor Federation has aroused new popularity for the Pittsburg organization, and its officers are now planning a series of events which will make the club a busy organization the coming season. The officers of the club, in conjunction with the Automobile Dealers' Association, have arranged for a series of lectures by experts from the various factories on the engines and parts of the different cars most used in Pittsburg. Endurance contests and road runs are also being planned for the spring and summer, and it is

proposed to extend the good roads campaign as fast as possible. At the last meeting of the club these officers were nominated to be voted on at the annual election February 18: President, George E. Turner, William N. Murray, Edward Kneeland; first vice-president, Phillip S. Flinn, George E. Painter; second vice-president, William N. Murray, E. J. Kent; third vice-president, Frederick Byers, W. A. Heyl; secretary, Paul C. Wolff; treasurer, George G. Glass; governors of the club, five to be chosen, Dr. J. A. Hawkins, Phillip S. Flinn, George E. Turner, William P. Baum, John C. Bragdon, C. M. Miller and William L. Dixon.

Capital City's Club Inaugurates Series of Smokers.

WASHINGTON, D. C., Jan. 28.—The spacious clubhouse of the Automobile Club of Washington was thronged with members and guests on the night of January 24, when the first of a series of smokers was given. More than two hundred cars were parked in front of the club house during the evening. President Caverly, Secretary Mark and Frank C. Berens had charge of the arrangements, and they carried out the details in a manner that won them much praise. During the evening a vaudeville entertainment was provided, several members of theatrical companies playing in Washington furnishing the bulk of the "stunts." A lot of new motion pictures of decided interest were also displayed. A buffet supper was served in the upper rooms.

Members of the Automobile Club of Washington are greatly interested in the proposed efforts of the District Commissioners to secure the enactment of a police regulation requiring all vehicles, whether used for business or pleasure purposes, to carry lights after dark. Some years ago the club made a determined effort to secure this legislation, but such a howl went up that the effort was abandoned. It is pointed out that many accidents occur on account of no lights on wagons and carriages after dark, and the commissioners believe that conditions now warrant some action along the line indicated.

Charleston Autoists Will Form a Club.

CHARLESTON, S. C., Jan. 25.—This city is about to have an automobile club, preliminary steps to organization having been taken at meeting just held at the rooms of the Commercial Club. A committee of five, consisting of J. M. Connelley, Norman H. Blich, E. W. Hughes, Dr. R. S. Cathcart, and M. B. Paine, was appointed to draft a constitution and set of by-laws, and prepare a plan for permanent organization which will be consummated at a meeting to be called in the near future.

Philadelphians Hear Lecture on Carbureters.

PHILADELPHIA, Jan. 28.—Over 150 members of the Automobile Club of Philadelphia gathered at the club house, 1409 Walnut street, last Saturday night to listen to a lecture on "Carbureters," by Prof. Charles E. Lucke, of Columbia University. After the lecture there was a short discussion of the merits of alcohol as a fuel and the best form of carbureter to use therewith. A banquet wound up the evening's entertainment.

CLUB DOINGS IN GENERAL.

WILKINSBURG, PA.—The Wilkesburg Automobile Club has joined the Pennsylvania Motor Federation.

WILMINGTON, DEL.—After a long lapse of inactivity the Wilmington Automobile Association has met and discussed plans for the coming season. There was no significant action taken at the meeting, but renewed activity is expected.

PHILADELPHIA.—The Automobile Club of Germantown will hold its annual dinner Friday evening, February 9. Robert P.

Hooper, chairman of the Highway Improvement Committee of the A. A. A., heads the club's guest committee, and will act as host for the occasion.

BROOKLYN, N. Y.—A. R. Pardington, chairman of the good roads committee of the Long Island Automobile Club, has chosen as fellow committee members H. S. Fullerton and Alexander Schwalbach, and the appointments have been confirmed by President Richardson.

LOS ANGELES, CAL.—Good work has been accomplished by the Automobile Club of Southern California this winter. The road to Santa Barbara from this city has been adequately equipped with enameled danger and guide signs, and the inland San Diego road has had a large number of the signs put into position.

YOUNGSTOWN, O.—Plans are being made by automobilists of Youngstown and Marietta to organize auto clubs in both cities. A. D. Thomas, of Youngstown, and L. L. Peddington, of Marietta, recently visited Cleveland, for a consultation with Secretary Asa Goddard, of the Cleveland Automobile Club, and both prospective organizations will accept the Cleveland club as a model.

NEW YORK.—At the last meeting of the board of directors of the New York Motor Club it was decided to place in operation initiation fee clause of the by-laws commencing March 1. A committee was appointed to arrange changes in the by-laws of the club, intended to simplify the executive work of the organization and at the same time widen its power for activity in many lines, such as legislation, good roads, contests, tours, etc. It is probable that the number of directors will be increased from nine to fifteen. A. G. Batchelder was elected first vice-president of the club, and will represent it on the governing board of the New York State Automobile Association. President Stevens has been named on the directorate of the A. A. A.

FIRST YEAR OF THE JERSEY LAW.

TRENTON, N. J., Jan. 28.—J. B. R. Smith, commissioner of motor vehicles for New Jersey, has submitted to Governor Stokes his report of the workings of his department since its creation under the Frelinghuysen law of last winter. One of the most perplexing questions with which the department has had to deal is the proper identification of vehicles. The report says that the ideal identification would consist of some device that can be plainly seen under any conditions of light or darkness from any reasonable distance or angle. Interstate registration has received attention, the proposition being made that each State accept the identification marks of the others, as, for example, a car registered in Pennsylvania with the mark 5000 Pa. would be given the same number in New Jersey and other States agreeing to the proposition. On the personal examination question the department finds a wide difference of opinion. It concludes that the personal examination accomplishes no good purpose, and might be superseded by an age limit, a declaration that the applicant is physically and mechanically competent to drive, and that he is acquainted with the automobile laws of the State. Contrary views also prevail on the speed limit, Commissioner Smith having a decided leaning towards a general proviso which prohibits any person driving a motor vehicle at a greater speed than is reasonable, having regard for the traffic and use of highways. Neither is the commissioner in sympathy with the suggested maximum gears, believing that the ease with which any gears can be altered would make it impractical from a mechanical viewpoint. Other suggestions are compulsory lights for all road vehicles; the trial of automobile offenders before a Court of Common Pleas, or some special court; provision for appeals in the matter of revocation of licenses and registration certificates; and more uniform and united action among the different police forces.

BELGIUM OPENS ITS NATIONAL SHOW.

BRUSSELS, Jan. 20.—Surrounded and escorted by staff officers, Prince Albert of Belgium officially opened the national automobile show in the Palais du Cinquantenaire. Being under the direct patronage of the King of Belgium, himself an enthusiastic automobilist, the opening had all the éclat of a Court ceremony: grenadier guards in full dress uniform, staff officers, members of the Government, industrious little Belgium's leaders of industry, in regulation dress suit, and not a small number of fair dames made up a brilliant group. Prince Albert has more than a smattering of automobile knowledge, and in his three hours' ramble through the big palace showed a deep interest in the leading national models. As an indication of the Prince's automobile enthusiasm it is interesting to recall that ten or twelve years ago he bought the first De Dion gasoline tri-car which ever appeared in Belgium; the machine had as strenuous a life as ever a De Dion knew.

Minute attention has been paid to the decoration and illumination of the hall, the effect being pleasing, notwithstanding that ten thousand of the 32,000 electric lamps refused to light up on the opening day. In very many cases French exhibitors have transported their handsome Paris stands to the Brussels exhibit, a fact which is very gratifying to the Belgian public.

Belgium constructors predominate, naturally, but French builders are present in large numbers; Germany and Italy are adequately represented; other countries have only one or two firms each. The home industry gives signs of rapid progress during the past year, the industrial motor especially receiving an enormous amount of attention at the hands of both builders and users. In general the Belgian automobile industry has followed very closely in the wake of France; but in the matter of light and heavy delivery vehicles the little royalty early forged ahead of its republican neighbor, and still maintains her lead.

Considerable attention is being given to the automobile for army purposes, and a delegation of staff officers will follow and report on the heavy vehicle competition to be held next April.

EARLY ENTRIES MADE FOR GRAND PRIX.

PARIS, Jan. 19.—Contrary to previous experience, entries for the Grand Prix race, to be held in June or July next, are being made early by French constructors. Already \$19,000 have been handed over to the sporting commission as entrance fees for three Bayard-Clement, three Darracq, three Motobloc, and one Corre, three Panhard-Levassor, three Lorraine-Dietrich, and three Renault machines. Of these the Motobloc and Corre are the only firms which have not figured in previous important long-distance road races. The Motobloc racers will have all the distinctive features of the firm's standard touring machines, will not develop more than 100 horsepower and will not weigh more than 2,200 pounds. It is expected that three Brasier, three Hotchkiss and two Civelli de Bosch machines will shortly be engaged, bringing up the French competitors to twenty-seven. Foreign firms have not yet shown themselves interested in the race, but Mercedes, Fiat, Itala, Rolls-Royce (British) and Germain (Belgian) are regarded by the club officials as almost certain starters. Thus the total number of competitors will be from thirty to thirty-five. No decision has yet been arrived at regarding the exact date of the race or the circuit on which it will be run. From some twenty or thirty, the list of suitable circuits has been cut down to four, each of which is being enthusiastically boomed by its not uninterested partisans. At present the Seine-Inférieure course is in the ascendency. Starting from Dieppe it follows the coast line to near Mers, descends south to Londinières, and runs up to Dieppe again, forming an equilateral triangle of about fifty miles. Its rivals are the Eure, Marne, and Aisne districts, each with courses averaging 55 miles. With a possibility of thirty entries for Grand Prix No. 1, and twice that number for Grand Prix No. 2, an exceptionally wide circuit is essential. The members of the Sporting Commission find a choice very difficult.

Although official regulations are not yet out, three Gillet-Forest machines have been entered for Grand Prix No. 2. This event will be run the day after Grand Prix No. 1 on a fuel allowance of 3.3 gallons per 62.1 miles.

IMPOSING VIEW OF THE BRUSSELS AUTO SHOW FROM ONE OF THE END GALLERIES OF THE PALAIS DU CINQUANTENAIRE.

ACROSS THE RIO GRANDE INTO MEXICO, LAREDO, TEXAS.

IN MEXICO WITH MR. GLIDDEN.

After 5,022 miles of safe and enjoyable travel since November 1, the date of departure from Boston, Globe Girdler Charles J. Glidden's Mexican trip came to a sudden stop December 31, when within fifty miles of the ancient city of the Aztec kings. After leaving Chicago, on November 22, Mr. Glidden and party used the railway tracks, his Napier car being fitted with special wheels with flanges, and his auto had the same status with the railroads over which he passed as a special train. He passed the Mexican border over the railway bridge at Laredo, Texas, and continued his journey southward toward the City of Mexico, which he figured would be reached the day before New Year's.

The story of the wreck of the car is best told in Mr. Glidden's own words: "We were running twenty-eight miles an hour," he says, "on a straight track, when a rock wedged in between the main track and a guard rail was struck by the flanges of the left wheels, and we jumped the rails and ran about ninety feet. The forward wheels collapsed and we were all spilled out, but no one was injured. Had not the wheels collapsed the car would have run up on a bank, overturned, and undoubtedly buried us all underneath, with serious results. I tapped the telegraph wire, put on a set of instruments that I was carrying, and immediately opened up communication with the train dispatcher at Mexico City, securing assistance in a short time in the shape of a special train. We arrived in the City of Mexico on the time planned, December 31."

Mr. and Mrs. Glidden have returned to Boston, and will continue their world's tour upon the completion of repairs to the

ONE TYPE OF MEXICAN HOME THAT IS FREQUENT.

car, which has been shipped to the Napier factory in England. They will resume their journey at Port Said, in Egypt, to which point, at the entrance of the Suez canal, the car will be sent when repairs have been made.

PENNSYLVANIA AUTOISTS ARE HOPEFUL.

HARRISBURG, PA., Jan. 28.—Improvements in automobile legislation are being sought by the Pennsylvania Motor Federation. The changes contemplated include more elastic speed law regulations, especially in country districts, where the present law is unnecessarily stringent; greater license for automobilists, with a strict accountability for offenses; a reciprocity between automobilists from other States, whereby visitors will not be required to take out a new license before touring through Pennsylvania, providing the State from which he comes extends the same privilege to Pennsylvania. State Highway Commissioner Hunter has included these proposals in his annual report to the State Legislature.

A BILL TO TAX AUTOS IN CONNECTICUT.

HARTFORD, CONN., Jan. 28.—A bill to tax automobiles annually \$1 per horsepower was introduced last week in the senate of the general assembly. This will apply only to cars registered in the State of Connecticut. The bill has been referred to the committee on rivers, roads and bridges. The proposed taxation measure has the endorsement of the Farmers' Association of the State, which always wields a strong influence in the general assembly, and there is a possibility of it being favorably reported.

PARIS TO LONDON AERIAL RACE.

PARIS, Jan. 20.—Flying machines being the latest things in existence, it was not to be supposed that the enterprising, competition-organizing Parisian journal *Le Matin* would remain indifferent to their development. Paris to London by balloon, for a grand prize in cash of \$50,000, twenty thousand of which were given by *Le Matin*, and \$10,000 each by the Marquis de Dion, M. Clément, of automobile firms, and M. Charley of Mercedes interests, was announced a few months ago. Plenty of time has been taken to study conditions, and it is only to-day that the official regulations have been made known. The big prize will be given to the proprietor of the machine traveling from Paris to London under its own power in the shortest time, where there are several competitors, or in any case within a 24-hour limit. The distance being about 220 miles, a minimum speed of over nine miles an hour will have to be maintained. Mishaps en route appear to be considered possible, for the regulations stipulate that the machine and its pilot must finish together. One finishing without the other will disqualify.

Whatever the weather conditions the first start will be made on July 14, 1908—the French national fête day. If the prize is not won, other starts will be made on the second Sundays in

COUNT DE LA VAULX'S FIRST DIRIGIBLE AIRSHIP.

As it appeared when hovering over the Sartrouville Plain, near Paris, on the morning of January 9.

August, September, and October. Descents may be made during the journey for filling gasoline tanks and taking up stores, but no outside propulsion aid must be given the machines. Arrival will be made by dropping a seal within a circle of 82 feet from a fixed point yet to be decided upon in the city of London. Any type of aerial machine is available for entry, but the motor must be of French construction.

RACING BALLOON MAY ENTER DUTY FREE.

Balloons engaged in the Gordon-Bennett International Aeronautic race at St. Louis will, by a decision of the Secretary of the Treasury, under date January 16, 1907, be allowed to enter the United States under bond. This privilege of free entry will be limited to balloons engaged for some race or specific contest, and will not cover exhibitions. A consular invoice must be obtained from the United States consul at the city where the balloons are shipped, and must be presented at the time of entry into the United States. The balloons must be exported from this country within six months from the date of entry.

J. C. McCoy, who will almost certainly be one of the three defenders in the Gordon Bennett balloon race, has been awarded a license as a pilot by the Aero Club. Mr. McCoy had already qualified as a pilot of the Aero Club of France. He is the first aeronaut to make a formal entry for the Lahm cup. A cup will probably be offered this year for women aeronauts.

Present Status of the Chicago Show. Historically considered, the rise and development of the show idea in the western metropolis is almost a repetition of what it has been in New York. Like the small beginnings that characterized the project in this city, there was a first abortive attempt at holding an automobile show, and in the case of Chicago this was of the open-air variety. It was a fizzle, but it did not discourage the promoter of the first successful show which was held but a year later than the first event of the kind, which occupied the floor at the Madison Square Garden in November, 1900. That was in 1901, at the Coliseum, and as the latter is a structure fully as large, if not larger, than the Garden, there was the same difficulty in piecing out the meagre exhibits to make some kind of a showing that would begin to fill it. With this exception, however, that the imported car had not reached the inland city at that time in anything like the numbers in which it was known in New York, so that there was a dearth of this material for the promoter to draw upon. Those who can recall the first event of the kind to hold forth in the Garden would not be apt to say that there were many imported cars on view, but no matter how small their number, there were some; there were considerably fewer at Chicago, if, indeed, there were any at all. The same expedient of making a track around the board floor on which to permit the cars to perform was resorted to with about the same results. In fact, even after there were more than enough cars and accessories to fill all the available space offered by the Coliseum, the exhibitors of the former were permitted to show them in action in the limited space afforded by their allotment, just to let the buyer know that they would run.

The rest is a matter of common knowledge—how the Chicago show has continued to expand, until in point of space occupied, as well as the total number of exhibitors, it is now superior to any held in this country. And its rise and growth have also been that of the city of Chicago as a market, or, more properly, as a distributing center, for a large part of the automobile output of the country. To a very great portion of the United States Chicago is east and that portion sends a large representation to the annual show, and it draws as well from the south and southwest, even across the border in Mexico. As a market with a large local demand it is second only to New York, as is evidenced by the rapid though sound financial development of its “automobile row,” and as one of the events of the season its show has come to be a matter of importance not alone to the local population but to automobile interests at large. The West demands special attention.

Encouraging Extent of the American Industry.

Statistics usually make dry and uninteresting reading, and the lesson they bear is more often than not forgotten ere it has had time to make any impression; nevertheless, there is nothing that reveals so surely the hand of progress, and for this purpose a complete list of the cars made in this country has been tabulated and is published in this issue. It shows, in condensed form, better than anything else possibly could, not alone the vast extent of the American industry as a whole, but the extremely wide range of types and prices that are offered to the American purchaser. From the diminutive runabout listed at a few hundred dollars up to the car selling at several thousand and upon which no expense nor ingenuity has been spared to make it not alone as modern, but as luxurious as possible, there is a wealth of variety such as seemed far beyond the wildest flights of imagination but a few years ago. Whether it be power, weight, multiplicity of cylinders or the reverse, or merely speed that the buyer sets up as his whole criterion in choosing a car, he will find his wants fulfilled. There are cars having all the way from one to eight cylinders; cars with less than 10 horsepower or with more than 50; cars at almost any weight desired and with any speed range or touring capacity that the most exacting of autoists could call for. To the observer who delves beneath the surface, the most surprising thing of it all and the one which shows better than anything else the firm foundation upon which the American industry is based, is the fact that these cars are built by their makers with few exceptions, and not merely assembled. Though the parts maker who is a specialist must ever be one of the strongest factors in the industry, the day of cars constructed wholly of stock parts of questionable value, cheaply assembled, is fortunately still a long way off. May it remain so.

Auto Sprint Racing Has Had Its Day.

A post-mortem of the Ormond-Daytona meet quickly unearths the fact that sprint racing is a thing of the past in automobile competition. To construct a car practically, capable of lasting not much beyond the mile, is a task of which any automobile manufacturer is capable by simply multiplying cylinders and adding surplus power. Mr. Stanley applied himself to the job, and let us admit that he succeeded in evolving a flying freak, worthless for any other purpose. But the buyer of automobiles to-day demands a car which can go the distance, and, therefore, if he is influenced by racing performances, he now looks to a Grand Prix or Vanderbilt Cup winner, and pays slight heed to a dash performer. If there are to be future meets over the famous Florida course, there must be a commanding event almost equal in importance to a big international road race, and it would appear that those connected with the Ormond-Daytona racing fully realize the situation which confronts them. A late winter or early spring event of the distance variety undoubtedly would be welcomed by those makers who would participate in the Vanderbilt and desire another opportunity for competition with the same cars.

FLORIDA MEET SPOILED BY FREAK SPRINTER

Which Startlingly Concluded Its Career, Nearly Killed Driver Marriott, and Ended Racing—Next Year Distance Events to Occupy Center of Stage and Sprints Secondary.

By. A. G. BATCHELDER.

ORMOND-DAYTONA, FLA., Jan. 26.—A steam freak, which just qualifies for competition under the present racing rules, spoiled the fifth meet on the famous ocean boulevard. This intermittent space annihilator—it was as capricious as a coquette in its brief flying moods—appropriating the center of the stage disproportionately to its scant utilitarian automobile value, discouraged the presence of cars built to go the distance, and caused the speed gathering to be a lamentable failure, sickening to those who had worked most industriously for success, and disappointing to the comparatively few spectators who came here solely for the racing.

How the Steam "Bug" Ended Its Career.

Then, as if glorying in the havoc which it had caused, this chortling, creepy, mechanical being abruptly, on Friday, ended the meet with a startling catastrophe which left it bestrewn in pieces over the sands, and gave its pilot the closest kind of a call from a horrible death. None too securely fastened, apparently, the forward part of the crimson-hued coat raised when a bump in the beach was encountered; Marriott lost or had inadequate control; the car skidded, then slid along on its side, rolled over several times, ejected its abnormal boiler, and wound up its career a complete wreck, with the driver

limp and senseless underneath. Marriott's escape was marvelous, and a source of much thankfulness. His injuries are minor, and he will be about in a few weeks after several broken ribs have mended and other scars faded from view.

January Dates Were Most Inconvenient.

The weather, as a whole, was ideal—a vast change from that which existed during previous meets, when fur coats were frequently in demand. But the week was inconvenient to the automobile trade, owing to the proximity of the Chicago show, and this kept away some entrants who might not have been deterred because of the exaggerated presence of the Stanley "Tea-Kettle."

The two combined completed the destruction of the entry list, which had its final blow when information came that Wagner and the 1906 Vanderbilt Darracq and S. B. Stevens and the 1905 Vanderbilt Darracq were eleventh hour withdrawals. To designate them as withdrawals might not be exactly correct, for it seems that no entry blanks were signed, nor fees paid. W. J. Morgan says he thought he had a distinct understanding with the American Darracq Company manager, even though the blanks were not signed. The latter must have considered the understanding void when

THE FLORIDA BEACH NEVER APPEARED TO BETTER ADVANTAGE WITH ITS ARTISTICALLY DISTRIBUTED GROUPS OF SPECTATORS

DRIVER BLAKELY AND HIS 70-HORSEPOWER AMERICAN MERCEDES THAT WON THE LION'S SHARE OF HONORS.

the entry list dwindled to such small proportions—and it is true that the only car of Darracq caliber in the opens was the American Mercedes. Another time the indefatigable Morgan says he will not consider any entry actually made until the blank is signed and delivered. All around, this is the better plan for all concerned.

And What of Another Year?

When the débris of the wrecked steamer, which had not been carried away by the insatiable souvenir hunters, had been removed, and it was learned that the unlucky—or rather lucky—Marriott was not badly hurt, the officials and pressmen gathered at the clubhouse for a mid-day luncheon given by the Florida East Coast Automobile Association. President Asa Paine, one who is not discouraged easily, and L. R. Speare, the conscientious referee of the meet, were at the head of the table. A serious discussion of the future Ormond-Daytona meet took place, the keynote of which was that the day of sprint racing in automobile competition had passed; that not only the makers, but the public placed greater value on a car that could go the distance instead of one specially constructed for a short dash.

The question of a program for the 1908 meet was referred to a committee to consist of Chairman Jefferson deMont Thompson, of the A. A. A. Racing Board; S. A. Miles, manager of the N. A. A. M.; M. I. Brock, assistant manager of

the A. L. A. M.; Alfred Reeves, manager of the A. M. C. M. A.; President Asa Paine, of the F. E. C. A. A., and W. J. Morgan, its New York representative. This capable set of men will hold a session in the near future, and something definite concerning the next year's meet will be announced early in the summer—early enough to give time to prepare.

"LICENSED" DAY AND "INDEPENDENT" REEVES.

The Florida Gold Cup, a 300-Mile Race.

One suggestion for the 1908 meet is a 300-mile race, 150 miles a day, for the Florida Gold Cup, which shall go to the winner without any qualifications. Its value would be not less than \$1,500. Only cars which participate in this event, and shall travel at least 100 miles, to be eligible for free-for-all record trials, which would take place on the fourth day of the meet, the third day being occupied with stock-car races of not less than ten miles. For the Gold Cup race there might be required stock chassis and specified cylinder capacity or fuel limitation, and perhaps all three. The committee will wrestle with the rules, which shall be issued early enough to give makers an opportunity to comply with conditions imposed.

The Gold Cup race would be a winter Vanderbilt cup affair, and the Ormond-Daytona beach furnishes an ideal place. Its straightaway is 15 miles, and could be lengthened to 20 miles, and loops might be constructed at the two ends at a small expense.

PAINE, THE DRUMMER.

100-Mile Race for Minneapolis Cup Star Race.

Proof of the interest in long-distance racing was supplied by the only real race of the meet—the 100-mile contest for the Minneapolis Cup—won by a newcomer to the lists, the American Mercedes, skilfully handled by diminutive Blakely, whose work with the Continental-tired car from Long Island City places him in the ranks of cup drivers. Getting away in the lead, outclassing its opponents, the American duplicate of the famous European car traveled the century without a skip or trouble of any sort, giving a consistent performance that commanded the attention of the onlookers. The Rolls-Royce, rated at 20-horsepower—the Mercedes is given as 70—which had had a hollow victory in the international touring car championship, owing to a slight engine trouble that left the Welch *hors du combat* for the moment, survived the "hundred," though some distance in the rear of the winner. A. L. Kull's Wayne, and Ralph Owen's New York-to-Florida pathfinding Oldsmobile were still pursuing the even tenor of their way when Referee Speare found it necessary to call them from the beach in order not to interfere with the other races. No matter how small were the fields, Clerk of Course Reeves called them according to the planned schedule.

About Some of the Other Races.

The Welch, with its bright green, was a convincing winner on Wednesday of the 20-mile American touring championship, its 22:32 4-5 being a record for fully equipped stock cars at the distance.

F. E. Stanley drove one of his own cars in the 10-mile open on Wednesday, running a fair second to Blakely and the American Mercedes. Marriott and the "Bug" figured as a starter, but went down and out at about a mile, with both cylinders out of commission.

The Wayne, with A. L. Kull at the wheel, had a look-in on Thursday, taking the 5-mile standing start for cars listing between \$1,500 and \$2,500.

Previous to its sensational disintegration on Friday, Marriott's "Bug" had been unable to better its :28 1-5 mark of a year ago. On Monday it did :38 3-5 in an effort that was handicapped by the incoming tide; Thursday the figures were :31 4-5; and Friday before the accident the first mile was in :32 4-5, and then came one in :29 3-5, which encouraged Marriott to believe that the next attempt would bring a new record. Instead of this his life hung in the balance.

THE TALK OF THE TIDE-MADE COURSE.

Captain C. E. Hutton, the Rolls-Royce entrant, made many friends, his unassuming manner of looking after his interests commending him to the officials generally, and his car was always ready when required.

Tire representatives in attendance were: Joseph M. Gilbert, general manager, J. L. Gibney, Philadelphia manager, and W. A. Rutz, sales agent, Continental Caoutchouc Company; G. A. Davidson, Diamond Rubber Company, and A. J. Wills, B. F. Goodrich Company.

George H. Day, general manager of the A. L. A. M., who is spending a vacation in Daytona as a guest of J. B. Moore, a Hartford-Floridian, was a daily spectator. Mr. Day looks rugged, and it would appear that he did not require any rest unless he so willed it.

First Vice-President George E. Sebring, of the Florida East Coast Automobile Association, Wednesday night entertained some of the officials at dinner in his palatial new home in Daytona. Mr. Sebring and his brother are responsible for building of Sebring, Ohio, where they have one of the largest potteries in the world. In the club handicap Mr. Sebring's Winton was rated a probable winner, but in some manner the man from Ohio failed to run one-two-three.

AMERICAN MERCEDES AND THE "BUG" STARTING IN TEN-MILE.

One of the pleasant functions of the week was the dinner given Tuesday night at the Hotel Ormond by Joseph M. Gilbert, manager of the Continental Caoutchouc Company, and A. L. Kull, manager of the New York branch of the Wayne. Mr. Gilbert naturally was elated that the all-conquering American Mercedes wore Continental tires.

Prominent trades people present included Ray Owen, sales manager of the Reo Motor Car Company; R. E. Olds, the maker of the Reo line; A. W. Church, of Wyckoff, Church & Partridge; John W. Haynes, who drove the Haynes in the Vanderbilt race; Walter C. Baker, American Ball Bearing Company; Ray P. Johnson, Warner Gear Company; F. A. Davis, formerly of Gray & Davis.

L. H. Perlman, New York agent for the Welch Motor Car Company, celebrated the victory in the 20-mile American touring car championship by a dinner, Thursday night, at the Hotel Ormond. Mr. Perlman is an enthusiast, and when two other concerns which were to share a freight car with him for transportation of autos to Florida withdrew, he refused to be influenced, and bore the entire expense. John Brodsky, a well-known New York lawyer, accompanied him, and was one of the speakers at the dinner.

The building of a loop at each end of the Ormond-Daytona course would be comparatively inexpensive because of the abun-

CAPTAIN HUTTON'S ROLLS-ROYCE THAT WON DISTINCTION

L. H. PERLMAN AND THE WELCH TOURING WINNER.

THE WINNING WAYNE AND ITS DRIVER, A. L. KULL.

dance of road material near at hand. It has been suggested that at the Ormond end at least—and perhaps at the Daytona turn also—the road would continue from the beach all the way across the narrow peninsula and strike the picturesque Halifax river road, with its abundance of tropical foliage, and then swing back to the ocean over the hard-shell thoroughfare past the Hotel Ormond, the guests of which could watch the race from its plentiful verandas.

The officials were both experienced and conscientious, but, unfortunately, they had little to do as compared with former meets; a schedule arranged each day was faithfully observed. Referee, L. R. Speare, clerk of course, Alfred Reeves, starter, John W. Haynes, timers, "Jack" Kerrison and Walter C. Baker and judge, S. L. Haynes, were always on deck, and F. E. C. A. A. Committeemen Allen, Gore, Sebring and Parkinson helped wonderfully. President Paine drove his Winton repeatedly in order to fill out in races.

F. E. Stanley, the creator of the "Bug," has no idea of resurrecting his famous steam sprinter; in fact, he does not hesitate to make the definite statement that the worth of a single fast mile or two has depreciated to such an extent that it is no longer worth while to build a car for this single purpose. Mr. Stanley intends to return the Dewar trophy to Sir Thomas Dewar, the donor, and suggest to him the advisability of offering it in a race for a longer distance, at least ten miles, and perhaps more. Mr. Stanley apparently has studied the Christie car, for he states that it is his intention to bring forth a front-drive steam car in the near future.

SUMMARY OF 1907 ORMOND-DAYTONA MEET.

Monday, January 21.

TIME TRIALS AT ONE MILE.

Stanley, 30-h.p.; F. H. Marlrott.....	:38 4-5
:28 1-5, record held by same car and same driver.	
Curtis, 2 1-2-h.p.; H. G. Curtis.....	1:05 2-5

Tuesday, January 22.

FIVE MILES, ALL CLASSES, STANDING START.

1. American Mercedes, 70-h.p.; E. B. Blakeley.....	4:25
2. Rolls-Royce, 20-h.p.; Capt. C. E. Hutton.....	
3. Stanley, 20-h.p.; H. Ernest Rogers.....	

FIVE MILES, ALL CLASSES, FLYING START.

1. Stanley, 30-h.p.; F. H. Marlrott.....	3:44 4-5
2. Rolls-Royce, 20-h.p.; Capt. C. E. Hutton.....	4:52 4-5
3. Stanley, 20-h.p.; H. E. Rogers.....	

ONE MILE-A-MINUTE AMERICAN TOURING CAR CHAMPIONSHIP.

1. Stanley, 20-h.p.; Frank Durbin.....	:53 3-5
2. Rolls-Royce, 20-h.p.; Capt. C. E. Hutton.....	1:09 2-5
3. Stoddard-Dayton, 30-h.p.; G. D. W. Rose.....	

FIVE-MILE MATCH RACE.

1. Stanley, 20-h.p.; H. E. Rogers.....	3:51 4-5
2. American Mercedes, 70-h.p.; E. B. Blakely.....	

QUARTER-MILE HIGH-GEAR SLOW RACE, STOCK CARS.

1. Stevens-Duryea, 20-h.p.; W. A. Adriance.....	1:13
2. Peerless, 30-h.p.; W. C. Baker.....	
3. Oldsmobile, 30-h.p.; Ralph Owen.....	

ONE-MILE SPECIAL MATCH.

1. Oldsmobile, 30-h.p.; Ralph Owen.....	1:37
2. Autocar, 20-h.p.; Asa Paine.....	1:39

ONE-MILE MOTORCYCLE RECORD TRIAL.

Curtis, 2-cylinder; H. G. Curtis.....	:53 4-5
---------------------------------------	---------

Wednesday, January 23.

20-MILE AMERICAN TOURING CAR CHAMPIONSHIP.

1. Welch, 50-h.p.; L. H. Perlman.....	22:32 4-5
2. Winton, 30-h.p.; Asa Paine.....	28:16
3. Wayne, 35-h.p.; A. L. Kull.....	

20-MILE INTERNATIONAL TOURING CAR CHAMPIONSHIP.

1. Rolls-Royce, 20-h.p.; Capt. C. E. Hutton.....	
2. Winton, 30-h.p.; Asa Paine.....	

TEN-MILE, ALL CLASS, STANDING START.

1. American Mercedes, 70-h.p.; E. B. Blakely.....	7:42 1-5
2. Stanley, 20-h.p.; F. E. Stanley.....	7:52
3. Welch, 50-h.p.; L. H. Perlman.....	10:55

ONE-MILE MOTORCYCLE MATCH.

1. Curtis, 2-cylinder; H. G. Curtis.....	:46 2-5
2. Indian, 2-cylinder; W. Ray.....	:46 3-5

Thursday, January 24.

100 MILES, ALL CLASSES—MINNEAPOLIS TROPHY.

1. American Mercedes, 70-h.p.; E. B. Blakely.....	1:26:10
2. Rolls-Royce, 20-h.p.; Capt. C. E. Hutton.....	2:02:35
3. Wayne, 35-h.p.; A. L. Kull.....	
4. Oldsmobile, 30-h.p.; Ralph Owen.....	
5. Welch, 50-h.p.; L. H. Perlman.....	

TEN-MILE OPEN HANDICAP.

1. American Mercedes, 70-h.p.; 15 sec.; E. B. Blakely....	13:59
2. Franklin, 30-h.p.; Dr. Stinson.....	14:34 3-5 ✓
3. Winton, 30-h.p.; Asa Paine.....	14:34 4-5

FIVE-MILE TOURING CARS, \$1,500 TO \$3,000.

1. Wayne, 35-h.p.; A. L. Kull.....	5:52 1-5
2. Stevens-Duryea, 20-h.p.; W. A. Adriance.....	

ONE-MILE MOTORCYCLES.

1. Curtis, 2-cylinder; H. G. Curtis.....	:46 2-5
2. Simplex, 2-cylinder; Wm. Ray.....	:46 4-5

Friday, January 25.

SIX-MILE HANDICAP, F. E. C. A. A. MEMBERS.

1. Cleveland, 30-h.p.; J. Laughlin.....	8:08 2-5
2. Cleveland, 30-h.p.; R. M. Bond.....	8:10 4-5
3. Stoddard-Dayton, 30-h.p.; G. W. D. Rose.....	8:47

TWELVE-MILE SPECIAL MATCH.

1. Rolls-Royce, 20-h.p.; Capt. C. E. Hutton.....	13:12 2-5
2. Franklin, 30-h.p.; Dr. Stinson.....	14:32 4-5 ✓

ONE-MILE RECORD TRIALS.

Stanley, 30-h.p.; F. H. Marlrott.....	:32 4-5
Stanley, 30-h.p.; F. H. Marlrott.....	:29 3-5

ALL THAT WAS LEFT OF THE STANLEY "BUG."

F. B. HOWER HEADS TOURING BOARD.

What the Touring Club of France has done for automobilists in the European republic, and how it has improved roads and hotels, protected historic sites, given information on tours, hotels and garages, used the weight of its 100,000 membership in legislative matters, and generally contributed to make touring easy and pleasant, is common knowledge. The Touring Board of the American Automobile Association intends to do as much for automobile travelers in the western republic. Under the chairmanship of Frank B. Hower, of Buffalo, who has just been appointed to the position by President Hotchkiss, the board will begin at once the collection of information of use to tourists, covering the present condition of laws and ordinances in force in the different States and cities of the country, the best routes between given centers, hotel and garage rates on such routes, and where they may obtain the most serviceable maps of any given territory. Dai H. Lewis, of Buffalo, has been appointed secretary of the Touring Board, and he will have charge of all the detail work, and will be in direct communication at all times with the office of the association in the Metropolitan Building, 1 Madison avenue, New York.

It is the belief of the new administration that the endeavors of the Touring Board in this direction will shortly put an inestimable value upon membership in the American Automobile Association not heretofore enjoyed, and from which benefits will be derived by American automobilists which will make membership in the A. A. A. a more valuable and essential asset.

Mr. Hower, the new chairman of the Touring Board, is an enthusiastic automobilist, is vice-president of the Automobile Club of Buffalo, of which he was one of the charter members, and is well qualified for this position, having rendered valuable service in connection with the management of the 1906 Glidden Tour. Mr. Lewis, the new secretary, is at present secretary of the Automobile Club of Buffalo, and in this position has established a touring bureau for the members of this club which is complete in every detail, and, owing to his extensive touring in this country, is especially well fitted for the work.

FEDERAL AUTO LAW TO BE ADVOCATED.

A strong forward movement is about to be made in the matter of inter-State automobile legislation. Charles T. Terry, the new chairman of the Law Committee of the American Automobile Association, and W. H. Hotchkiss, president of the A. A. A., have drawn up a bill on this subject, which will be introduced at the present session of Congress. If it should prove that a Federal law is liable to conflict with the rights of individual States, then efforts will be concentrated toward securing as uniform an automobile law as possible throughout all the States in the Union. It is hoped to pass a law whereby a motorist may certify to some department or bureau of the National Government that his automobile is duly registered in his own State, and that it is his intention to use the machine in other States. Upon complying with such regulation a certificate might be issued exempting him from additional registration.

In view of the growing complication of the automobile legal situation, this move is bound to meet with the approval and support of all automobilists. A meeting of representatives from all the automobile clubs in the State of New York will be held shortly, probably at Albany, when a definite policy on the motor legal situation will be mapped out.

INSURANCE BILL FAVORABLY REPORTED.

ALBANY, N. Y., Jan. 29.—Assemblyman Young's bill, authorizing the formation of insurance companies to insure against loss or damage to property resulting from accident to a duly licensed automobile, and against loss or damage to property when caused by an automobile, was favorably reported by the assembly insurance committee to-day.

KNOX STOCKHOLDERS ELECT DIRECTORS.

To celebrate the completion of the recently erected additions to the plant of the Knox Automobile Co., at Springfield, Mass., the annual meeting of the stockholders, which took place on Tuesday last, the 22d inst., was in the nature of an informal housewarming. The directors elected for the coming year are: E. H. Cutler, W. E. Wright, A. E. Smith, P. Murray, A. W. Cutler, H. G. Farr, W. H. Chase, M. J. Greenwood and George W. Bennett. The directors then reelected the present officers—E. H. Cutler, president, and W. E. Wright, vice-president. Under the Massachusetts law the secretary and treasurer are elected by the stockholders direct, A. E. Smith and H. G. Farr being continued in these posts. Following this, the directors elected the executive committee, which consists of E. H. Cutler, W. E. Wright, A. E. Smith, H. G. Farr and G. W. Bennett. The treasurer's report for this past year showed a surplus equal to 13 per cent. of the capital stock.

An inspection of the plant followed, the company having practically doubled its facilities during the past few months, so that it now has a daily capacity of four touring cars and one truck. The most recent addition is a four-story and basement building measuring 75 by 200 feet, while the new foundry is one of the largest in New England. It is of steel and reinforced concrete, even the sashes being of iron. All the bronze and aluminum castings used on the Knox cars are made here. The new body and trim shops have also been planned along the most modern lines.

VERMONT WILL IMPROVE ITS ROADS.

MONTPELIER, VT., Jan. 29.—The Vermont Legislature has passed a law providing for the improvement of public roads throughout the State, and the appointment of a State highway commission. The new law provides that the Governor shall appoint a State highway commissioner, whose term of office shall be two years from the date of his appointment, and who shall have control of and direct the expenditure of all moneys appropriated by the State, or apportioned to cities, towns, or villages for highway improvement. He shall appoint each year a supervisor in each county in the State, who shall assist him in supervising the expenditure of State money to be used for the permanent improvement of the main thoroughfares and most important roads in each town, the selection of roads being made with the main purpose of securing, so far as possible, trunk lines of improved highway from town to town, and to important local railway stations. For this purpose the sum of \$50,000 annually was appropriated, and under certain conditions a town may have free of charge the services of a competent road engineer.

PALM BEACH MOTOR BOAT REGATTA.

PALM BEACH, FLA., Jan. 29.—The Palm Beach Power Boat Association races successfully opened to-day with a substantial entry list, good racing, and plenty of enthusiasm. The handicaps were based on the rating measurements of the American Power Boat Association, but on the following days the actual performances of the boats are to govern. The bulk of the honors went to *Simplex VIII.*, owned by H. Broessel, Jr., of New York City. This new craft captured three of the five events. E. J. Schroeder's champion *Dixie* looked like a sure winner from scratch in the Class B event, but her bearings becoming overheated she was stopped to prevent being disabled for the remainder of the week.

AERONAUTS FROM SPAIN FOR AMERICAN RACE.

President Cortlandt Field Bishop, of the Aero Club of America, has received a cablegram from the Aero Club of Spain, naming Captain A. Duani, Lieutenant Herrera, and Señor Salamanca as entrants in the international balloon race to be held at St. Louis October 19. These three are the same ones who represented Spain in the 1906 race for the Bennett Cup.

AN INCIDENT OF THE AUTO SHOW.

"Say, young man," said a venerable-looking old gentleman, approaching an attendant, immaculate in the faultlessness of his evening toilet, who was gracefully posing in the foreground at one of the principal exhibits of cars at the show last week. "Are you connected with the blank exhibit?"

The good-looking salesman—a college graduate who has recently made his debut in the business of talking automobile, felt somewhat hurt that anyone should question his standing, but replied in the affirmative.

"Well, then, I want you to show me the differential of your car and explain its advantages," went on the visitor.

"The differential, you say; h'm, the differential, is it," mused the young man.

"Yes, yes, the differential. Not the differential calculus nor the differential tariff; the automobile differential. Where is it put and what does it do?—that's what I want to know."

"Well, now—oh, just step this way, please. No, not to that bare car, to this limousine—this way, over here."

"You see, my son, he knows all about automobiles," went on the old man, "and he's finally persuaded me that I ought to have one, but he says 'don't you go and buy any car that hasn't got a good differential on it. If you do,' he says, 'you're bound to have trouble. The first thing you know, when your car is running smoothly along the street you're going to skid and side swap something,' whatever he means by that."

"Oh, skidding, you say," replied the young man, feeling relieved, but keeping his weather eye out for that haven of refuge in all cases of embarrassing questions—the technical man of the firm.

"Well, we'll equip your car with any style of non-skid you desire, such as we have on this car here, for instance. And isn't that limousine a beauty?"

"But the differential isn't put in the tires, is it? My son told me it had steel cog wheels in it and was put underneath the car where you didn't see it."

"Oh, yes, you *mean* the differential," broke in the young man, as if he had discovered something quite novel.

"That's what I've been talking—"

"Just step over this way," exclaimed the young man in a business-like manner giving his inquisitor no further opportunity for expression by leading the way to another part of the exhibit.

"Now this here—this (oh, hang it! Why did I flag French) this—"

"Chassis," suggested a third party, who had been noting the young man's increasing embarrassment.

"Yes, this here chassis—I never can remember French," he added, apologetically. "This chassis"—lingering on the word—"will show you all about the differential and how it works."

"Will it—can it talk?" amusedly asked the old man. "Don't go away, it may need your help," continued the inquirer, and his would-be enlightener, who would have been only too glad to escape, wiped away the perspiration that had gathered on his forehead under an opera hat and set about elucidating the differential and its mysteries.

"Four speeds and reverse, selective type, direct drive on the high, no gears in mesh," he began.

"Well, but what are you talking about?" interrupted his hearer in a mild tone of surprise.

"Oh, yes, the differential. I thought you understood that was the subject of our conversation at the moment. Were you thinking of any other part of the car?" he inquired solicitously. Being assured on this point, he went on.

"Well, here we have the differential you have been inquiring about, four speeds and reverse, selective type, direct drive on the high, no gears in mesh, chrome nickel-steel shafts and gears running on ball bearings, aluminum case running in oil—running in oil," he repeated, striking a snag in the rehearsal of his lesson.

"But what has that to do with the wheels, and how does it prevent you from 'side-swapping' something when the car skids?"

inquired the old man in a puzzled tone. "What do you work this brass lever here for?—to prevent a collision?" (taking hold of the gear-shifting lever.

The young man wearily mopped his brow once more, though the Garden was cool at the time, and as he was doing so caught sight of the designer of the car who had just entered the booth. There was no need of a distress signal—the technical man took in the situation at a glance. He walked over and was introduced to the inquisitive visitor who wanted to see the differential before buying a car. This formality completed, the young man suddenly remembered that he had an engagement elsewhere.

NON-STOP THOMAS SETS A NEW RECORD.*

BUFFALO, N. Y., Jan. 28.—The non-stop Thomas flyer arrived in Buffalo last Friday morning about 5 o'clock, and left Saturday morning at 8 o'clock for Chicago, where the flyer will be kept running during the Chicago automobile show, which closes February 9. Ernest Kelly was at the wheel. Kelly's first run ended on Wednesday near Utica, when, because of the necessity of using gasoline purchased at various country stores, his carbureter became clogged, and the engine stopped after running continuously for 21 days, 3 hours and 29 minutes. This record will probably stand for some time, as it eclipses the former non-stop motor record of 200 hours, and also sets the highest mark for reliability of performance, as not one adjustment was made on the car from the time it started.

Word was received in Buffalo yesterday that Kelly and his crew were snowed in twenty miles east of Erie at 10 o'clock Saturday night. John Cowling, of Philadelphia, who is alternating with Kelly at the wheel, was doing the guiding. Kelly and his crew went to Erie by train, but hurried back to the point where the car was snowed, and aided the shovel brigade. Although the car was stopped, the engine was still chugging away.

While in Buffalo, Kelly said the engine was running better than when they started, and, barring accidents, would be in Chicago by the middle of this week. He said the roads were bad, ruts were deep, and the ground hard and frozen.

MAXWELL FUEL TEST PROVING SUCCESSFUL.

WORCESTER, MASS., Jan. 30.—Climatic conditions have not been favorable for the three Maxwell cars making the comparative fuel test from New York to Boston. Leaving Columbus Circus at 8:45 o'clock on Monday morning a successful run was made to Hartford, arriving at 8 o'clock in the evening. The next morning a start was made for this city and after a hard run, owing to the deep snow, the machines were garaged at 5 o'clock in the evening. The automobilists were met by representatives of the Worcester Automobile Club and enjoyed the hospitality of the club during dinner and the early hours of the evening. Since leaving Meriden, Conn., the worst road conditions have been encountered; frequently the cars sank into the soft snow almost up to their axles. Notwithstanding, the trio kept well together, gasoline, kerosene and alcohol all proving equal to the task. The only trouble causing delay was with tires. Two rear shoes had to be replaced, one at Springfield and the other at Worcester, the damage in both cases being done by twisting the chains when passing over street railway tracks. To-day the start was made for Boston.

LEON RUBAY MOVING UP TOWN.

The last of the original establishments of West Thirty-eighth street, New York City, is about to join the uptown movement. Leon Rubay, the well-known importer of French sundries, has leased the entire four-story building at 1697 Broadway, and is having it refitted to meet the requirements of his business. The ground floor will be used as salesrooms and offices, the second floor will be a showroom, the third floor will be a repair department for coils and magnetos, etc., and will be one of the best equipped shops for the care of ignition appliances in the city. The top floor will be used as a laboratory.

RULES FOR A. C. G. B. I. HEAVY CAR TOUR

LONDON, Jan. 24.—The Races Committee of the Automobile Club of Great Britain and Ireland has lost no time in issuing the conditions governing the new touring car event for 1907, as soon as it was found unworkable to hold the proposed contest concurrently with the Tourist trophy as a kind of subdivision. The object of the competition is the development of ideal touring cars such as are usually fitted with covered bodies and of the horsepower required by the ordinary users, as opposed to the racing car, and is not necessarily a race between existing standard types. The horsepower and consequently the speed are limited by fixing a definite allowance of fuel for a given distance. The event is open to cars of all nationalities and must take place between May 1 and October 1, the definite date to be fixed by February 1.

We take the following from the regulations for the contest, the minimum distance of which is 250 and the maximum 400 miles: The fuel to be used will be provided by the club and shall be a petroleum spirit of a specific gravity of 0.715 to 0.725 at 60 degrees Fahrenheit. It will be supplied for practicing purposes should competitors desire to use it. For 1907 the allowance will be a gallon to every 16 miles for the Isle of Man course and an equivalent amount for a different route. The car specifications are as follows: Driving wheels no less than 36 inches in diameter; tires on driving wheels no less than 920 by 120 mm.; track no less than 4 ft. 6 in.; distance from dashboard to front edge of back tires no less than 5 ft. 9 in.; platform behind dashboard no less than 8 ft. 6 in. long, to be covered by the body. There must be a clearance of at least 8 inches from the ground when the car is fully loaded. The total load to be carried by the chassis shall not be less than 2,240 pounds. Such ballast as may be necessary to bring the total load carried by the chassis up to 2,240 pounds must be provided by the competitor in form of lead securely fixed

to the floor and back seat boards, and of this weight 224 pounds shall be carried on the back seat boards. The body must be substantially constructed and easily removable. A wind screen must be fitted to every car, not more than 12 nor less than 6 inches from the back of the front seats and behind them. The top of the screen shall not be less than 8 feet from the ground nor the width less than 5 ft. 3 in.

Mud guards must be fitted to front and rear wheels; the steps must be continuous with the guards, which may only be attached to the chassis.

Every competing car must show that it is capable of being driven half a mile a 12 miles an hour or less on the level on the top forward gear and without the manipulation of the clutch. It will also be required to show that it is capable of being stopped, restarted, and ascending a hill of about 1:6 on a forward gear. A limited number of attempts will be permitted. Between the start and finish of the race the driver and his mechanic alone shall be permitted to assist a car, and no stores, supplies (except water), spare parts, or tires shall be taken on to the car during the race. The driver and his mechanic only shall be on the car during the race. Not more than two cars by one manufacturer will be accepted; the order of starting will be decided by ballot. The entrance fee for 1907 is £30 per car, of which £10 is payable on day of entry and the remainder on or before May 1. After this date, entries are received at a rising scale of £2 per week until a month before the date of the event.

Cars will be weighed with empty tanks; any car arriving after the time limit fixed will be disqualified. Every car which completes the whole distance will be re-weighed and fuel tanks, water tanks and lubricating reservoirs will be emptied by the club. Forms of application and for the necessary specification of cars will be forwarded from headquarters, 119, Picadilly, London W.

WHAT IS DOING IN EUROPE'S CAPITAL OF AUTOMOBILING

By PHARE.

PARIS, Jan. 24.—Thirty liters of gasoline for every 100 kilometers of distance constitutes the new and principal clause in the regulations for this year's Grand Prix race in France.

M. Clemenceau, the Prime Minister, acting in his cabinet capacity of Minister of the Interior, has just granted to the Automobile Club de France authority to run "a grand speed race" on a closed circuit of roads in France in 1907. Application to the minister (who is branded by the Opposition as the Dictator, the governmental, anti-Godhead, responsible for the movement to crush religion out of France), with a certain period of suspense, was only a formality. It was a foregone conclusion that the permit would be granted—refusal in the face of France's "greatest industry" would cause a crisis, auto, if not ministerial.

With permission to use 100 liters of petrol, the automobile firms entering machines for the race will not feel that they are being narrowly restricted. This quantity will amply answer the appetite of a racing monster, so that the contest is not likely to resemble a touring jaunt to Jersey City. A sort of minority committee in the French auto world has been advocating a reduction of racing machine powers. Many numbers of this coterie are constructors of vehicles that are very infrequently arrested for "scorching."

After all, why shouldn't automobiles be handicapped in races? Horses are handicapped, cyclists are handicapped, and many automobile manufacturers are handicapped in their work of producing machines to compare with those of their competitors in the trade. Limiting the fuel consumption to a certain quantity gives everybody a chance to start scratch, so that the man who comes up the road with a smaller quantity of gasoline prac-

tically grants himself the opportunity of starting behind scratch, hence, so much the worse for him.

Thomas A. Edison, whose close relationship with automobilism is widely known on account of that very small electric battery which has not yet been used to run the biggest automobiles, is to be honored in France, contemporary with his celebration, en famille, in America, of his fortieth year as an inventor. M. Emile Durer, a local author of reputation, who figured as envoyé from President Carnot when Mr. Edison was invited to come to Paris on the occasion of the exposition of 1889, has written an "electric" play, embracing chief events and episodes in the life of the Wizard. This play will be sung, danced and pantomimed. It is to be called "Edison," and the music has been composed by a "grand musician," whose name has not yet been divulged. "Edison" will be produced at one of the leading Paris theaters in the form of an electric fairy scene, and "on lines of elaboration heretofore unheard of."

Among the "unpatriotic" Americans who have recently purchased automobiles in Paris are Mr. Chisholm, president of the National Paper Company, 40-horsepower Bianchi; L. H. Spaulding, of New York, 40-horsepower Rochet-Schneider; Frank Gould, 14-horsepower C. G. V.; Stewart Browne, 70-horsepower Rochet-Schneider; S. S. Keyser, 20-horsepower Renault; Ernesto Fabbri, 75-horsepower Mercedes; George Gould, 10-horsepower Renault; Frank Tilford, 40-horsepower Rochet-Schneider; Mrs. Katherine Giles, of Pittsburg, 24-horsepower Fiat; Captain Bell, of New York, 24-horsepower Panhard; Jefferson Seligman, 40-horsepower Rochet-Schneider; the Misses Brice, of New York, 20-horsepower Renault.

AUTO SUPPLY COMPANY'S FINE GENERAL SALESROOM.

AUTOISTS HAVE DEVELOPED A NEW INDUSTRY.

Almost as rapid as the development of the automobile itself has been the extension of accessories, clothing and the thousand and one things for the car and its driver which modern refinement now asks for as necessities. Only a few years ago the manufacturer supplied the naked car, the hardware dealer stocked a few accessories, and at the clothier store some feeble attempt was made to clothe the automobilist. It was a transitory stage and had all the disadvantages of transition. The Auto Supply Company realized this, and made a vigorous and successful attempt to change the old order of things. It is no exaggeration to say that in their new store at 1733 to 1737 Broadway, New York, the automobilist will find everything necessary, useful or ornamental for himself or his vehicle. On the ground floor, with a 37 1-2-foot frontage on Broadway, are the car accessories. Lamps, tires, horns, speedometers, sparking plugs, electrical appliances, and all the stock fittings which every self-respecting car carries about with it are there in endless variety. Not only the fittings themselves, but every screw, bolt or clip required to fix them in position can be obtained. If the automobilist is luxuriously inclined, and hankers after elegant fittings, ingenious appliances, or the elegancies of handsome closed bodies, he will find them all under the same roof.

On the floor above a handsomely fitted-up room, with a 75-foot frontage on Broadway, the automobilist himself is provided for. A quarter of an hour spent with the clothing expert and you will be fitted out from head to foot in the most suitable auto

SECOND FLOOR, WHERE AUTOMOBILE CLOTHING IS SOLD.

clothing for winter or summer use, for racing or touring, for driving or for use as a passive traveler. The lady autoist is equally well provided for, and will find here auto clothing with a chic which betrays the work of the most skilled home and foreign designers.

Each department of the Auto Supply Company is in charge of an expert. The big stock of tires of all makes is handled by a man who has had long experience in tire manufacture; the hardware department is supervised by a practical tool-maker; the different accessory lines are each taken charge of by salesmen specially versed in that particular line; the clothing section is in the hands of men and women who have studied closely the sartorial art in its application to automobiling. Thus the buyer in selecting from an infinite stock has always the aid of highly-trained specialists.

RELIANCE TRUCK MAKES LONG WINTER RUN.

To publicly demonstrate the value of their commercial vehicle, the Gearless Transmission Company, of Rochester, N. Y., arranged a mid-winter run from Detroit to Chicago. The vehicle was a two-ton Reliance truck, equipped with gearless transmission, and a two-cycle engine, which started from Detroit last Saturday evening. On Monday morning Coldwater, Mich., was passed; on Tuesday morning South Bend, Ind., was reached, and on the same day Chicago was entered in triumph. The object of the tour was fully attained, for the Reliance truck, with its two-ton load, proved that it could be successfully driven over long distances in the middle of winter and deliver goods more promptly than shipments could be made by rail. This is one of the first, if not the first, attempt to drive a large commercial vehicle from one city to another in the heart of winter, and it shows something of the progress that is being made in this department. The truck is now being exhibited in space E No. 9 at the Chicago show, in the Armory Building.

A STATEMENT BY THE FORD ATTORNEY.

"Few people realize how much is at stake in this Selden litigation," said R. A. Parker, attorney for the Ford Motor Company, in the famous suit. "One hundred millions of dollars is a conservative estimate of the amount that is at stake in this growing industry and which would be jeopardized should the original contention of the licensed association be sustained. There are some thirty-three to thirty-five members of the licensed association still in business. Of the independent makers there are now considerably over one hundred concerns producing automobiles; and the independents now make over 60 per cent. of all the automobiles made in America and Europe. Could the ridiculous claims of Selden to a basic patent which would apply to every automobile built to-day—thirty years after the patent was originally applied for—be sustained by the higher court, all these concerns would be bankrupt. But the freedom with which astute and conservative investors put their money into the independent automobile enterprises is proof that this litigation, while formidable in appearance, is not taken seriously by those who ought to know. In short, there is no longer any doubt in the minds of the independents that Ford will win a clean-cut decision, and as a basis for this confidence we need only cite the evidence of the chief witnesses for that side, Selden himself, Dugald Clark, Bentley, and others in which they make damaging admissions which show that the A. L. A. M. no longer hopes, or even asks for, a decision so broad as to uphold the basic claims on which at first so much stress was laid, but that the most they hope for is some kind of decision upholding some kind of a patent, to which those concerns which were, through an appeal to greed and lust for monopoly, induced to become parties to the original scheme, may still be made to pay tribute."

COMPACTNESS IS FEATURE OF THIS CLUTCH.

A multiple disk clutch that will hold a 40-horsepower car and yet is so compact and light that it can be removed and held on one hand, is something new. The principle is one that has been tried for several years in Europe and improved upon by the Aerocar Company, of Detroit, until all objectionable features

NEW AEROCAR CLUTCH IS LIGHT.

have been removed, and a clutch, that is said to be ideal in its operation, obtained. The whole consists of 42 light thin disks, alternating steel and bronze. The 21 steel disks are made of high carbon steel and are forced to revolve with the flywheel. The 21 bronze disks are made of special phosphor bronze of the very finest quality and are fitted in grooves on the terminal of the transmission shaft. The disks run in dust-tight casings in a bath of oil. This prevents wear and permits of a gradual taking up of the load as the film of oil is forced from between the disks as the clutch is let in. By the use of the alternating steel and bronze disks, the cutting (which has always occurred sooner or later where only one metal is used) is entirely overcome and failure to work obviated.

Between each plate and carried on the steel plate are relief springs which make the action almost instantaneous. In the past, multiple disk clutches have had four, six and even eight compression springs placed at equal distances around the edge. In this new Aerocar clutch there is but one and that at the center working on a thrust ball bearing. The smallness of the whole is interesting. By removing six bolts from the flywheel and disconnecting the universal joint it can be taken out and easily held on one hand. It is very sensitive in operation and yet will start a standing load from the high gear on a hill. The clutch will be fitted on the new Aerocar models and will greatly enhance the value of those machines.

BRITISH AUTO TRADE BUOYANT.

Consul F. W. Mahin, of Nottingham, England, writes that the largest business on record is being done this year by the automobile and bicycle factories of England. The feeling in automobile-making circles is so buoyant and sanguine that confidence is expressed of entirely supplanting foreign cars with British in process of time. It would be impossible just now, for the home factories cannot supply the home demand. But new factories are being erected and old ones enlarged, and within a few years the aggregate plant is expected to be able to meet all demands. It is hardly possible that the present boom will continue unabated for any great length of time, and so there is danger of undue inflation and overproduction, and a repetition of the disaster which followed the bicycle boom a few years ago.

Large plans are being laid for this year in the motor-car branch, when a prodigious trade is expected. It is intended to produce a greater range of automobiles, and particularly cheaper grades, from 10 to 35 per cent. lower in price than the usual output of British factories. Several cheap makes have stood the test of experience, and these will be made specialties. While catering to a more extended custom, the production of such cars is aimed specially at France, whither British purchasers of this grade of stock have always turned. It is hoped that the bulk of this trade can now be kept on the British Isles.

FORD RUNABOUT PRICE RAISED A HUNDRED.

DETROIT, MICH., Jan. 28.—The most startling recent development in the local trade is the announcement by the Ford Motor Co. of an advance in price of the popular \$500 runabout. The same identical car will continue to be manufactured, but the public must pay an extra hundred for each of the runabouts sold in future. It is the \$600 machine hereafter, and the wise ones of the row predict that even another advance before long would be no surprise.

The Ford people give as the reason for an advance in price, that materials have so increased in value that it would have been impossible to turn out a runabout of such class as the Ford, at the old figure, without great loss to the factory.

Mr. Ford is off on an extended visit to California, but Vice-president Couzens says that the raise has been quite beneficial to the factories trade. "We have been simply swamped with orders in the past few days," said he. "People who have been holding off, expecting to get a car on spring delivery at the old price have simply stamped our way to get under the wire in time." This condition was anticipated by the Ford people, who held off making the announcement of the increase till the last moment.

The situation is interesting in view of the fact that another Detroit-made runabout is about to enter the field vacated by the Ford. The Brush runabout is to be a \$500 one, at least such was the announcement. From all accounts the Brush looks a pretty good proposition for the money, and the action of the Ford may indeed give the new concern a firm foothold, if a car of the class of the famous four-cylinder runabout can be turned out for \$500. The Brush will be shown for the first time at the Detroit show.

The report that the Winton Motor Carriage Company, of Cleveland, would open a sales branch in this city has been confirmed by Charles B. Shanks, sales manager for that company. A commodious and excellently equipped garage, such as the Winton maintains at the present time in New York, Boston, Philadelphia, Pittsburg, Cleveland, Chicago and London, will be seen here in the near future. The idea is to cater to Winton patronage, and assure satisfactory "up keep" of the Cleveland-made cars.

RATHER A UNIQUE GATHERING.

It is somewhat unusual to see any number of the Vanderbilt Cup race drivers together in any one place other than the course. The occasion depicted is that of the welcome extended to Wagner during his recent visit. He is shown sitting beside Elsie Janis, with Joe Tracy and Al Poole on the running board; Ralph Mongini forward; Walter Christie and George Robertson behind, and Vivet, Wagner's mechanic, at the rear wheel, the Simplex being the car used in the race scene on the stage.

ELSIE JANIS AND THE VANDERBILT CUP DRIVERS.

A MASSACHUSETTS TWO-PASSENGER RUNABOUT.

In bringing out its two-passenger runabout for 1907 it has been the aim of the Cameron Car Company, of Brockton, Mass., to produce a machine at once light, powerful for its weight, simple and not liable to mechanical derangement, durable and withal of very moderate cost. The result is an exceedingly smart runabout weighing but 900 pounds, but nevertheless carrying a four-cylinder motor that develops 16 horsepower at 1,000 revolutions a minute. The motor is air cooled, with the valves, all of which are mechanically operated, placed with their stems horizontal, the inlet valves on one side and the exhaust valves on the other. Long rocker arms extend from the crankcase, where their lower ends are acted upon by the cams, to the valves, which they actuate directly. These long rockers have the advantage of working without the long push-rods often used with overhead valve gear, and their length makes the movement on the pivots, which are attached to the cylinders by studs, very slight, insuring long wear. The spark plugs are screwed into the tops of the cylinder heads, and the timer is carried by a vertical shaft gear-driven from one of the camshafts, and is on the same level as the plugs, so that the wiring is short and direct.

But the most noteworthy feature of the car is the transmission. This was illustrated and described in *THE AUTOMOBILE* for November 8. Briefly, the entire transmission is mounted on the casing of the rear axle, which is of the live type, and is inclosed in an extension of the bevel gear and differential casing. The bevel pinion on the rear end of the propeller shaft meshes with a bevel gear on a short countershaft, and on this countershaft are three spur gears, of different sizes, which are adapted to mesh with a large spur gear carried on the differential casing. In changing from one speed to another the gears are not slid in and out of mesh, like ordinary sliding gears, but the countershaft is first moved away from the axle laterally, unmeshing the gears; then the gears are slid along until the proper one is in position and the lateral movement of the shaft is reversed, meshing the new combination. There are no more gears in mesh on the low speed than on the high. The reverse is obtained through an intermediate pinion. There are three forward speeds, the highest three to one, the intermediate four and a half to one, and the lowest seven to one.

Oak is used for the framing of the car and also of the body; the front axle is of I-beam section, and the rear axle of the type in which the wheels run on ball bearings on the ends of the tubes. Front wheels run on combination ball and babbitt bearings. Front and rear wheels are 28 inches in diameter, with 2 1-2-inch tires, in the regular equipment, but 3-inch tires will be fitted at an additional expense. With regular equipment, which includes oil side lamps, tail lamp, horn and tools, the price is \$750; with the special equipment, including 3-inch tires, actylene searchlights and generator, and a removable sloping rear deck, the price is \$850.

LYTLE AND THE PRESIDENT.

Herbert H. Lytle, the well-known driver of Pope-Toledos, was received at the White House by President Roosevelt this week (Monday). "The President was delighted," said Lytle, "and had me go into full detail about all the modern improvements installed in the 1907 Pope-Toledo. The President showed great interest in all the new features discussed and said that at his first convenience he would be glad to have me show him Washington by night in my 50-horsepower Pope-Toledo touring car. Even though his time is so completely taken up with important matters of State, he is far from being uninformed when it comes to mechanics, and I think he knows a car from bonnet to tail lamp."

"HANDS ACROSS THE SEA" IN AUTO SPORT.

A pleasant little exchange of felicitations recently took place between A. Darracq, the well-known French designer, and Henry Ford. M. Darracq was the recipient of a widely published interview with Mr. Ford, touching on the outcome of the Vanderbilt Cup race, in which the latter frankly stated the foreign car deserved to win, and, narrowing it down to the winner, praised the Darracq product. M. Darracq gave the article to the European journals for publication, and it was widely read and commented on in foreign trade circles. In acknowledgment of this courtesy on the part of Mr. Ford, M. Darracq writes his American confrère as follows:

"I have been deeply touched at the congratulations which you have been good enough to extend me on the occasion of the victory of our car in the Vanderbilt Cup race. Your praise is the more appreciated, as it emanates from one whose reputation is well known in Europe. I wish to assure you that the delicacy of your sentiment is appreciated, and I wish to thank you with all my heart. French cars will doubtless again meet American cars in an international contest. I hope you will be represented and that the meeting will always be in a friendly and sportsmanlike spirit as in the past. I thank you again for your kind words, and send you in return my best wishes for the success of your cars for the season of 1907. Please accept, dear sir, the assurance of my most distinguished regards. (Signed) A. Darracq."

NEW MOTOR LAWS IN SWEDEN.

The new motor laws long threatened for Sweden came into force on New Year's Day, and, in the main, resolve themselves into a wholesale restriction of speed. Towns and villages may only be traversed at a maximum of 15 kilometers in daytime, while the country's limit is fixed at 25, but after dusk only 10 kilometers are permitted both in town and country. Only persons over 18 years of age may drive a car, and must possess an official license. In Stockholm whole streets are forbidden territory to cars, and it is generally recognized that the unskillful setting up of the new act will do a great deal of harm and little good.

TWO CUP RACERS ALREADY UNDER WAY.

PHILADELPHIA, Jan. 29.—There is now being constructed by Jos. Parkin & Son, of this city, a car which is to be entered in the elimination trials for the next Vanderbilt race. It has six cylinders and is rated at 120 horsepower. Howard M. Ambler, of the Bergdoll-Ambler Co., is also building a cup racer and announces that it will be on the road in April next.

ISOTTA FRASCHINI RACES SHOWN AT OLYMPIA, LONDON SHOW.

NEWS AND TRADE MISCELLANY.

The Ciralsky building at 317 South St. Joseph street, South Bend, Ind., has been leased by the Tincher Motor Car Company, of Chicago.

Wing Brothers, proprietors of the American Automobile Company, of Tacoma, Wash., have moved into their modern concrete garage at 204-9 St. Helen's avenue.

Pierce & Isbell, the new agency for the Baker Electric Company, just opened at 1413 Michigan avenue, Chicago, announce that they will show five types at the coming Chicago automobile show.

R. E. Olds, president and general manager of the Reo Motor Car Company, of Lansing, accompanied by his wife, is now yachting about Florida waters on board his magnificent yacht the Reopastime.

A new garage is being built for the Reliable Automobile Company at Pacific avenue and Seventh street, Tacoma, Wash. Halstead House, a landmark, has been removed to make way for the improvement.

An organization has been formed in Brooklyn under the title of the Long Island Motor Trade Association. B. D. Underhill, of the Brooklyn Motor Supply Company, is active in the formation of the new body.

J. R. Thomas, the Maxwell agent in Washington, D. C., has leased for a term of years the large garage and salesroom at 1028 Connecticut avenue, and has removed from his former salesroom at 1319 L street, N. W.

A new make of automobile has been placed on the market by the Sinclair Scott Company, of Baltimore. The machine, to be known as the Maryland, has a 24-horsepower four-cylinder engine. Its selling price is \$2,500.

During the week of the Chicago show the Rushmore Dynamo Works will install nine 18-inch electric navy searchlights on the roof of their Chicago store, 1328 Michigan avenue. The store is only one block from the armory.

For the first time the entire Pope plant at Hartford is being devoted to the production of Pope-Hartford machines. Overtime is being worked to keep up with the strong demand, and from eight to ten cars are being shipped every day.

Contract for the steel work for the big Maxwell-Briscoe automobile plant at Newcastle, Ind., has been let to the J. D. Smith Construction Company. The contract calls for 1,200 tons of structural steel work, and the cost will be \$86,000.

Enlargements are being made by the Aetna Bottling and Stopper Company of their premises at 54 Peck street, Providence, R. I. The company has one of the largest repair shops in the city, and has recently acquired the local agency for the Grout gasoline car.

J. C. Cook, of Long Beach and B. L. Brown have purchased the interests of C. H. Kay and Phil Dorland in the Electrical Construction Company at 1126-1130 South Main street, Los Angeles. All Pope-Waverley models will be handled, and electrical work undertaken.

A ten years' lease has been secured by the American Locomotive Company on the entire sixteenth floor in the proposed

Cortland building of the Hudson Tunnel Company, at Church and Cortland streets. Floors in this structure will have 26,000 square feet of rentable space.

The Belle Isle Auto Company, Detroit, Mich., has secured a two-year franchise to operate an auto-'bus service across Belle Isle bridge and around Belle Isle. The fare will be 3 cents and 15 cents respectively. Four 18-passenger and three 36-passenger 'buses are being built at the Detroit machine shops.

These changes have been announced in the Jackson Auto Company, 312 W. Ninth street, Kansas City, Mo.: C. Boyd Richards retires as president, and is succeeded by W. A. Frank. Mr. Richards has sold his stock. F. L. Bumgardner is vice-president and treasurer. J. E. Halstead continues as secretary.

In printing the description of the new eight-cylinder Hewitt car, which appeared in the show issue of THE AUTOMOBILE, January 17, the price was given as \$5,500. It should have been added that this was for the car with a limousine body, the selling price being \$4,500 with a regulation touring body and equipment.

Application for a charter has been made to the Secretary of State by the Spartanburg Automobile Company, Spartanburg, S. C. The named capitalization of the company is \$5,000, and its incorporators are: Messrs. F. L. Bryant and Charles Parker. The proposed company will do a general automobile and supply business.

An interesting overland trip has been made by W. E. Kibbe, of Hartford, Conn., from Hartford to Ormond, Fla., in an 18-horsepower Columbia light touring car. Mr. Kibbe drove the car from Hartford to New York, and from there shipped it by boat to Jacksonville, Fla. From Jacksonville he drove overland to Ormond Beach, arriving just in time to see the opening races.

George H. Strout, of the Electrical Vehicle Company, expresses great satisfaction at the results obtained with the new Columbia multiple jet carburetor. The device really consists of two carburetors in one, designed to run the car to the greatest advantage at whatever speed is desired. The two work together, requiring no more adjustment or care than a single carburetor of earlier patterns.

Countess Hoyes, of Fuime, Hungary, has recently ordered a fully equipped 20-horsepower two-cylinder Maxwell car, which was shipped to her from Colonel Pardee's New York agency. Countess Hoyes is a granddaughter of Whitehead, of torpedo fame, and is accordingly an American by descent. This order is significant of the progress that the American automobile manufacturer is making in competition with the European makers.

Notwithstanding that it is only a year ago that the Lozier Motor Company took possession of their new four-story and basement building at the corner of Fifty-fifth street and Broadway, it has found it necessary to materially increase the facilities of its New York establishment. A lease has been taken on the entire third floor of the adjoining Pope building, which will give an increase of 7,000 square feet. A recent addition has been made to the works at Plattsburg,

N. Y., in the form of a building 60 by 160 feet, increasing the assembling and testing facilities materially.

At the annual meeting of the H. H. Franklin Manufacturing Company the following directors were elected: H. H. Franklin, E. H. Dann, John Wilkinson, Giles H. Stilwell, Alexander T. Brown, W. C. Lipe and Frank A. Barton. Inspectors of election: H. W. Chapin and John G. Barker. The directors elected the following officers: H. H. Franklin, president; Giles H. Stilwell, vice-president; Frank A. Barton, secretary; H. Barton Webb, treasurer. Executive committee: H. H. Franklin, Giles H. Stilwell and John Wilkinson. The report showed that the company had its biggest year in 1906, with prospects for a trade this year that will exceed the capacity of the plant.

An unusual record has been established by a set of Goodrich tires attached to the Oldsmobile in which Ralph Owen, of Cleveland, and a party of friends recently made a trip from New York to Florida, with a total load, including passengers and baggage, of about 4,000 pounds. The route lay over all sorts of roads, some so bad that ox teams would not travel over them. Upon arriving at Jacksonville it was found that the wheel chains, which were new on leaving New York, were completely worn out. An examination of the tires, however, showed that they were still in excellent condition after their 1,500-mile trip. As there had been no serious punctures en route, the air with which they had been inflated in New York was still imprisoned in the tires on arriving in Florida.

A special meeting of the stockholders of the Selden Motor Vehicle Company was held recently to vote on a proposition to classify the capital stock of the company, amounting to \$500,000, into preferred and common stock. The proposition was to divide the stock into 2,500 shares common, of the par value of \$100 a share, and into 2,500 shares of preferred, of the par value of \$100 a share. It was proposed to give the preferred stock a preference over the common stock in the assets of the company, and that the holders of such preferred stock shall be entitled out of surplus net profits to cumulative dividends not exceeding 7 per cent., in preference and priority to any dividends on the common stock. The entire proposition was carried. Building work on the East Rochester plant will be begun at a very early date.

A consolidation has been effected between the Correspondence School of Automobile Engineering, of Flatiron Building and 40 West Sixtieth street, and the New York School of Automobile Engineers, of 146 West Fifty-sixth street. Both concerns have been in existence on a substantial basis for over a year, the New York School of Automobile Engineers specializing resident instruction, while the Correspondence School devoted itself to the sort of business its name implies. As a result of the amalgamation a choice of either form of instruction or both in combination is made available. R. E. Olds, R. M. Owen and Robert H. Montgomery have transferred their interests. It is understood that Victor Lougheed will only remain long enough to put the consolidated concern on a satisfactory basis. In future the only address will be Fifty-sixth street.

NEW AGENCIES ESTABLISHED.

The Winton agency has been taken up by the Baltimore Motor Carriage Company.

Agencies for the Northern, Elmore and the Babcock Electric have been placed with the Mar-Del Automobile Company of Baltimore.

The Baltimore agency for the Wayne car has been secured by the Commercial Auto and Supply Company, at 862 North Howard street.

P. H. Greer, the Los Angeles agent for the Mitchell Company, has taken up the agency for the Marvel runabout, an \$800 car built at Detroit.

At 251 Jefferson avenue, Detroit, the Motor Sales Company has opened a new store for the handling of De Luxe and Queen cars. The interests of the company are being looked after by O. R. Baldwin and H. S. Goudy, two well-known business men of Detroit.

A new agency is about to be opened in Pittsburgh for the sale of the Matheson car, made by the Singer Sewing Machine Company at Wilkes-Barre, Pa. The agency will probably be managed as a branch of the Central Automobile Company of Cleveland. Edward J. Schellentrager is identified with the Pittsburgh office.

PERSONAL TRADE MENTION.

C. F. Green has been appointed Michigan manager for Witherbee Igniter Company.

Robert J. Firestone has been appointed sales manager of the Firestone Tire and Rubber Company, with headquarters at Akron, Ohio.

The superintendent for Meteor Automobile Works, Davenport, Iowa, is now E. Huber, late of Huber Automobile Company, Mich.

Stanley Brooks has taken up the position of Michigan manager for the Continental Caoutchouc Company. Marcus Allen has succeeded him at the Automobile Equipment Company.

Having resigned his position with the Crawford Automobile Company, W. W. Taxis, of 1840 North Park avenue, Philadelphia, is open to take up a position either at factory or as manager or assistant manager of branch house.

P. E. Hawley has resigned from the office of president of the Automobile Equipment Company, 260 Jefferson avenue, Detroit, in order to devote his entire time to the interests of Brandenburg & Co., of which he is a partner.

J. M. Gilbert, general manager, and James L. Gibney, Philadelphia representative of the Continental Caoutchouc Company, have returned from Florida. Continental tires were well represented on the winning cars at Ormond last week.

Henry Ford is enjoying a midwinter holiday jaunt in California in one of his big six-cylinder cars. He is accompanied by Mrs. Ford, his 12-year old son, Master Edsel, and Mrs. Ford's parents. The party will tour California from San Francisco to San Diego, and will visit the Lick Observatory on Mount Hamilton.

Among the principal speakers at the first monthly dinner of the New York Advertising League, held at the Aldine

Association, 111 Fifth avenue, New York City, Tuesday evening, was Robert L. Winkley, manager of the Publicity Department of the Pope Manufacturing Company. Mr. Winkley's talk was a subject of much favorable comment.

✓ H. H. Thorp, formerly of Franklin Automobile Company, and later with the Aerocar concern, is now sales manager for Deere-Clark Motor Car Company, Moline, Ill. He has placed agencies with Atlas Automobile Company, 102 West 107th street, New York; Bond Brothers & Co., Boston; Wm. Gilmon, Philadelphia; Davenport Automobile Co., Davenport, Ia., and others.

The White Company, of Cleveland, announces that Albert R. Warner has been made secretary of that concern. Mr. Warner has for nearly two years been in charge of the various White agencies throughout the country. He will continue his old duties in addition to shouldering the responsibilities entailed by his new position. Mr. Warner is a graduate of Cornell University, and is well known in Cleveland business circles.

✓ Arthur H. Robbins, formerly connected with the H. H. Franklin Motor Car Company, has succeeded Percy Owen as manager of the New York branch of the Aero Company. Mr. Robbins, who has been connected with the Ford and Pope companies, is planning an active campaign, and will undoubtedly increase the popularity of the Aerocar in the Eastern States. Mr. Owen recently withdrew to form the Percy Owen Motor Car Company in New York City.

NEW TRADE PUBLICATIONS.

Glide Automobiles, manufactured by the Bartholomew Company, Peoria, Ill., are described by text and engravings in an elegant catalogue produced by that firm.

Bouton Motor Company, 1675 Broadway, New York, give a brief description of Pullman cars in a recently issued folder. Their complete catalogue can be had upon request.

Smith & Mabley's new booklet "The Great Two," is a tasteful production descriptive of the well-known S. & M. Simplex cars. With it is an original souvenir postcard for those who have the postal habit.

All types of Waltham Orient automobiles are examined in general and in detail in the new catalogue of the Waltham Manufacturing Company, Waltham, Mass. Interesting particulars are given on what it costs to run a Buckboard.

Some idea of the extent to which long-distance coolers have been adopted will be gleaned from the Long Manufacturing Company's catalogue. Illustrations are given of the Long coolers fitted to a number of well-known cars and commercial vehicles.

"Stop Skidding" is a booklet describing Percy F. Megargel's trip across the Continent three times on Weed chain tire grips. It is interesting as descriptive of what an automobile can do, and incidentally points out the advantages of Weed Chain Grips.

"Sparks for Motor Ignition" is the title under which the Semi-Dry Battery Company, Newark, N. J., presents useful information on electric appliances for

automobiles. The man who wishes to be complete master of his automobile should obtain this pamphlet.

Archer & Co.'s new catalogue is an attractive booklet describing the automobiles built in the famous gun factory. It describes the Hotchkiss car in a way that is interesting to everybody, and with an interesting introduction by George Dupuy. The pamphlet is really worth reading. The printing and decorations are excellent.

The automobilist who contemplates a tour in France should secure a copy of "Automobile Formalities in France," distributed by Archer & Co., American agents for the Hotchkiss car. It is an elegantly produced booklet, compiled by the parent firm, and gives just the information the foreign autoist should have on how to secure a driving license and attend to other formalities in France.

"Touring Abroad" is an interesting little pamphlet put out by Smith & Mabley, Inc., and descriptive of touring in foreign lands as conducted by that firm's new European touring department. The new idea in touring Europe is that this well-known concern will provide a 30-horsepower Simplex touring car, seating six persons and chauffeur, for trips on the Continent. Smith & Mabley assume all responsibilities and attend to all annoyances of securing licenses, customs affairs, etc. A two-month's trip of 6,000 miles through France, Germany, Spain and Italy is planned.

One of the most luxurious and elegantly produced catalogues ever devoted to the automobile is just to hand from the Locomobile Company of America, Bridgeport, Conn. Produced in a chaste style in black and red, with numerous half-tone engravings, the whole is a masterpiece of the typographical art, and a book which will be turned over with interest by all, whether interested in automobiles or not. By text and cuts the various parts of the chassis are presented to the reader. Then follow scenes from the Vanderbilt Cup race, in which the Locomobile made such a good showing, half a dozen pages of illustrations show the Loco. touring in different parts of America or taking part in endurance contests; the next page and the reader is following the Loco. over Normandy's perfect roads and amid Scotland's wild beauty; still a little further and the Loco. is in France's chateau district, near the blue waters of the Mediterranean, and under Italy's azure skies. Another page and the car is on the streets of Brooklyn and New York. Those who have not seen the catalogue ought to see it; those who have will keep it.

RECENT INCORPORATIONS.

International Auto Company, El Paso; capital stock, \$10,000. Incorporators, Julius A. Krakauer, Charles M. Barber, of El Paso; Juan M. Salazar, of Chihuahua, Mex.

Iron City Automobile Company, Pittsburg, Pa.; to manufacture, sell, repair, lease and store automobiles. Incorporators, J. J. Seelie, John Weaver and P. S. Chambers.

Silver Lake Park Company, Atlanta, Ga.; to establish a club and resort for automobilists; capital stock, \$100,000. Incorporators, C. H. Ashford, E. C. Thrash, James R. Gray, William Owens, Hoke Smith, B. M. Blount, H. C. Bagley, M. F. Amorous, H. C. Stockdell, W. C. Caldwell, A. W. Farlinger, T. B. Lumpkin, E. Rivers, H. C. Ashford and Robert L. Berner.

INFORMATION FOR AUTO USERS.

French Socket Wrenches.—Socket wrenches in sets of six, eight and ten sockets of different sizes respectively are being imported from France by the Motor Car Equipment Company, 55 Warren street, New York. In one style the socket pieces are straight with two hexagonal sockets of different size, one at

HANDY IMPORTED WRENCHES.

either end, and in the other set the socket pieces are bent at a right angle to facilitate working in awkward corners. The socket pieces are made of well-tempered steel tubing, and are bored transversely near the middle to receive a small, straight steel handle for turning the wrenches. This handle is formed into a punch at one end, and at the other is upset to prevent the head pulling out of the socket hole.

Rushmore Searchlights.—For the past seven years Rushmore lamps have been produced without any material change in their construction, and that they still

THE 1907 RUSHMORE SEARCHLIGHT.

maintain their position is shown by the extraordinary number of car manufacturers who make it their regular equipment. The special feature of these lamps is the extremely short focal length of the lens mirrors, by reason of which the burner can be placed very

close to the front edge of the mirror, thus permitting the latter to utilize the maximum percentage of light. On account of its proximity to the burner, the

SKELETON VIEW RUSHMORE GENERATOR.

lens mirror is made of the toughest annealed lead glass, which stands the heat, and whose index of refraction is higher than that of the window glass commonly used. The Rushmore generator differs from others in having an independent movement to shake the carbide basket. As is well known, when the carbide basket is rigid with the generator a large portion of the dust fails to shake through, with the result that the lime blankets the carbide. This is prevented in the Rushmore by hanging the basket from opposite corners and suspending a lead weight by a spring over one of the free corners. The automatic water feed is controlled solely by the gas pressure.

Ever Ready Carbureter.—The distinguishing feature of this instrument is the combination of two carbureters in one. One carbureter is connected with a small brass tank filled with volatile naphtha, and is used solely for starting. The other is thrown into operation as

EXTERIOR VIEW, NEW EVER-READY CARBURETER.

soon as the engine has warmed up, and is then capable of running on any kind of fuel, irrespective of whether it is low-grade gasoline, kerosene or alcohol. Another feature is that it promptly starts the engine in any kind of weather, whether it is zero, wet, foggy or dry. The Auto Improvement Company, 316 Hudson street, New York City, is marketing this interesting article.

Diezemann Shock Absorber.—The value of a well constructed shock absorber no longer needs to be pleaded. By adopting it as a standard equipment of their machines some of the world's best automobile manufacturers have given public testimony to its value in securing easier riding at higher speeds and decreasing the strain put upon engine and other mechanical parts. The Diezemann shock absorber, manufactured by the company of the same name at 1311 Hudson street, Hoboken, N. J.,

SECTION OF DIEZEMANN SHOCK ABSORBER.

is well known to the American public. In 1907 two sets will be constructed, one for cars over 1,800 pounds, the other for cars under this weight. The only structural change is that the bronze case is made heavier to resist torsional strain, and the grease reservoirs in the steel spindles are being made larger. Briefly, the Diezemann shock absorber

consists of a bronze casing containing fiber friction discs and a steel friction spindle bolted to the side member of the chassis, the friction discs being packed in grease and by means of a screw plug may be adjusted to yield the desired resistance. A copper seated set screw holds the adjusting plug in position, and a lever joins it up to a connecting link pivotally secured to a plate mounted upon the vehicle, axle or spring. All friction surfaces are packed in grease and are absolutely dust-proof.

An Improved Spark Plug.—To overcome one of the common defects of spark plugs, short circuiting due to a deposit of carbon, the Splitdorf plug has been devised. Its feature is the longest insulating surface possible without increasing the size of the plug in any way. A mica bushing is formed on a taper consisting of lateral windings of mica, composed of sheets, the full length

SPLITDORF IMPROVED SPARK PLUG.

of the insulator. This mica bushing is inserted into a small bushing or nut, and is forced to a solid formation by the central electrode. The mica bushing is so extended as to create an insulating surface of one inch. Outside of this a porcelain insulator is used, which increases the insulating surface to one and three-quarter inches in length. In addition to their greater length, the insulated parts are so designed as to break up the carbon deposit. Another desirable feature is the small amount of gas space inside the plug, thus preventing excessive heating. The plug is handled by C. F. Splitdorf, 17-27 Vandewater street, New York.

Automobile Tops.—At this season of the year some protection against rain, snow and hail is absolutely essential if automobiling has to retain its charms. The open touring car has manifest advantages over the heavy closed vehicle, providing it has some kind of protection against winter storms. The complete line of tops built by the Vehicle Top and Supply Company, St. Louis, are calculated to supply this need. Lightness, strength and graceful lines are all combined in this series, which include simple extension tops, runabout tops, full and three-quarter backs, fastened either by rear joints or front straps. Interesting features are front and side roll curtains by the use of which an open body can be entirely inclosed.

Imported French Rims.—Clincher rims that are different in some important particulars from those of domestic manufacture are being introduced in this country by the National Sales Corporation, and sold in New York as one of its specialties by the Motor Car Equip-

PEUGEOT CLINCHER RIMS FOR 1907.

ment Company of 55 Warren Street. Aside from the special quality of the metal used by the well-known firm of Peugeot Frères, the chief difference noticed in the French rims made by them is the saving of weight with no sacrifice of strength by the simple means of making the rim thin where it is supported from below by the wheel felloe, and increasing the thickness at the edges where strength is needed to hold the beads of the tire and to withstand occasional contact with stones, car tracks, curbs, etc. The edges are well rounded and smoothed off to prevent chafing of the sides of the tire, while the gradual thinning down of the metal from the edges to the base of the rim reflect the careful designing that is so noticeable in all parts of the best French automobiles and their fittings.

Improved Turntables.—Among the season's novelties in automobile sundries is a new and improved model of the Weber Turntables. The previous model looked like a pair of huge roller skates joined together by metal stirrups on which rested the tire of the automobile wheel. In the new model the tire rests in a trough-shaped steel casting mounted on three pairs of cast iron rollers pivoted like casters, one pair at the front and two pair at the rear. At the front end of the trough-shaped casting is an incline up which the wheel of the car will roll easily. The over-all measurements of the turntable are 28 inches in length and 16 inches in width, and the casting is large enough to take any size of tire. The turntable is amply strong to carry

WEBER TURNTABLES FOR GARAGE USE.

the weight of the heaviest touring car. A set of them is used under the rear wheels of a car to facilitate handling in a garage. The retail price is \$20 per set. The agency for them is held by the Motor Car Equipment Company, 55 Warren street, New York City.

A Few Facts About Asbestos.—One of nature's most wonderful and unique products is asbestos, a material, which, in spite of its extensive use, is comparatively unknown to the general public. Prior to 1850 it was looked upon principally as a curiosity, although Charlemagne (Roman Emperor from 800 to 814 A. D.) is said to have had a tablecloth made of asbestos, which he cleaned by throwing into fire.

There are two varieties of commercial asbestos, known as Amphibole and Chry-

sotile. The former is used only to a comparatively small extent, as the fibers are short and without tensile strength, and are, therefore, not suitable for manufacturing many of the asbestos products. Amphibole is used to some extent in cements, but is not well adapted even for that purpose. Chrysotile, on the other hand, has a strong and silky fibre, which adapts it for such materials as asbestos fabrics, household utensils, theatre curtains, clothing for firemen, etc.

In Germany asbestos is known as steinfachs (stone flax), and the miners of Quebec give it quite an expressive name—pierre coton (cotton stone).

Asbestos is mined in open pits, similar to stone quarries, and although it is found in all parts of the world, the mines in Quebec, Canada, are the most famous, yielding about 85 per cent. of the world's supply of chrysotile. Probably the largest of these mines is that owned by the H. W. Johns-Manville Company, of New York. In 1879 the output of the Quebec mines was 300 tons, which has steadily increased year by year to 50,000 tons in 1905.

Gasoline Gages.—The Triumph Gasoline Gages, manufactured by the Boston Auto Gage Company, Boston, are designed specially for both automobile and motor boat tanks. The gage is magnetically controlled by a metallic

TRIUMPH JR. HANDY GASOLINE GAGE.

float, and may be connected with the top of a tank. The intermediate collar on the tube, shown on illustration, is screwed into a bushing connected with the top of the tank, and the gage tube is extended above the collar to the deck of the boat, where the head of the gauge having the

FLUSH DECK GAGE FOR MOTOR BOATS.

pointer will be protected by the usual deckplate. Lifting the lid of the deckplate shows the pointer that indicates the amount of gasoline in the tank. All gages are made of rustless material.

CHICAGO'S SHOW PRODIGIOUS AND PROSPEROUS

Combining Licensed and Independent Concerns, Numerically It Leads All Previous Exhibitions; Artistically It Presents a Most Pleasing Industrial Picture

By A. G. BATCHELDER.

CHICAGO, Feb. 6.—It is the show of the season that is taking place in the Coliseum and the First Regiment Armory. Circumstances may have made it so, but, nevertheless, it is so, and the astonished East must remove its goggles and doff its headgear to the energetic West, even though the raw weather requires the wearing of bulky fur coats, which coverings are mighty handy in traveling through "Pneumonia Lane"—an unavoidable, disagreeable feature—which connects the Coliseum and the Armory.

There are a hundred and a few more actual makers of automobiles housed in the two buildings; a scant few are newcomers, several of which give indications of obtaining a good foothold in the business. Chicago has always produced several additions to the industry, and a year later these ones have usually asked for an Eastern debut at the A. C. A. show.

The Show Includes the Best.

But the Coliseum-Armory show excels both the Madison Square Garden and Grand Central Palace affairs because it takes the greater part of the two metropolitan exhibitions, failing to obtain only a few of the "foreigners," and thus retaining more space for the American industry, which from the outset has held the West secure from the efforts of the importers of foreign cars.

It cannot quite be said that the "Licensed" and "Independent"

makers are all placed side by side in this "Sixth Annual Automobile Show," for in the membership of the National Association Automobile Manufacturers the "Seldenites" predominate in some degree, and so it must follow that they would have more of the commodious Coliseum and less of the somewhat inconvenient Armory, wherein, it so happens, only Smith & Mabley, Inc., and the Buick Motor Car Company hold forth as the unlucky ones

of the A. L. A. M. camp. In the Coliseum the fortunates include the White steamer, Baker, Babcock and Woods electrics, and Thos. B. Jeffery & Co., and such A. M. C. M. A. familiars as Maxwell-Briscoe, the National, American Mercedes, Stoddard-Dayton, Mitchell, Premier, Wayne, St. Louis, Smith, and Holman. All these intermingled with such names as Autocar, Cadillac, Corbin, Columbia, Elmore, Franklin, Knox, Locomobile, Lozier, Matheson, Oldsmobile, Packard, Peerless, Pierce, Popes of three kinds, Royal, Stearns, Stevens-Duryea, Studebaker, Thomas, Waltham, Walter and Winton, give an all-round significance which was lacking both in the Palace and the Garden.

The annex of the Coliseum is an improvement over the Armory, and those who make the journey through the draughty covered passageway have to take a view of its occupants, which includes Cleveland and Reo, Darracq and Mercedes, Harrison and Welch,

Columbus and Glide, and several others. Upstairs the annex spaces are light and comfortable, if less get-at-able.

All things considered, the allotments were accomplished in such manner as to do the best possible for all, the accessory folks having better facilities for exploiting their wares than in either previous big show. The onlooker must be given opportunity of seeing thoroughly and listening in comfort if his interest tempts him to linger in the range of the expositors' voice.

Wanted a Large Building for a United Show.

Once more comes the oft-repeated wish that there were in some large city of this broad land a building like the Grand Palais, of Paris, wherein all the leading makers could display their wares and thus demonstrate the magnitude of an industry that soon will be second to none in money invested and actual work to the country at large.

Decorative Scheme Finds Great Favor.

Of course, there will be some to dissent—prejudiced Easterners, the Chicagoans will call these critics—who will not admit that Manager Miles in his decorative scheme has seen the Swiss hand of the Garden and accomplished a more artistic touch in the dressing of the homely Coliseum and the ordinary Armory. Harmonious and appropriate seems the frequent face of Mercury at the steering wheel, and the fleeting youngster fits into the picture with a dash that typifies the spirit of automobiling. A score of large canvases illustrating touring and racing scenes add greatly in impressing the character of the exhibition, and the plaster friezes over the stands and around the balcony are automobilistic, which is the keynote aimed at in general. Green carpets with red borders and yards upon yards of red and white bunting, and a yellow sunset-tinged sky, which, alas, discourages photography, figure in the Coliseum decorating. An airship hangs from the center girders—here is a copying of A. C. A. recognition of the nearness of aerial motor navigation—and an abundance of American flags assists in the blending of the bright colors. Out in the Armory the ceiling has a green and white concealment. Some thirty thousand dollars is said to be the sum expended in beautifying the two buildings, and no matter if there is a bit of exaggeration in the statement, the work has been excellently done and meets with a more or less general approval.

A year ago the café feature in the Coliseum was too prominently indicated, and this time the entrance to the underground place of

refreshment and drinkables is unobtrusive, possesses an attractive entrance and has been entirely rehabilitated, much to the satisfaction of the patrons of the show and all others concerned.

Sales Promise to Be Substantial.

The Chicago show will do much business, judging from reports that appear based on fact and discarding the usual press agent stories of "output entirely sold." It is true that the two New York shows practically completed the disposal of the cars of a score of established concerns, but it must be kept in mind that the Chicago exhibition brings to this city innumerable agents from the Middle and extreme West, even out to the Pacific Slope. These men are from prosperous sections, where people want automobiles and are capable of buying cars of the costliest kind. The average Easterner has an idea that beyond Chicago there isn't much left of the country worth considering, but, if in the automobile trade, he only needs a trip here and an inspection of the list of agents who pour in from the boundless West at show time to cause him to revise his ideas very materially. Foreign cars may not sell in large numbers, for your Westerner is above all things American in what he thinks and always in what he buys. Importers, recognizing this fact, have devoted their main efforts to the East, which buys with less patriotism—and frequently pays more.

Some Day the Now Curious May be Buyers.

It may be the erroneous impression of an Easterner, but a study of the crowds which have daily filed into the Coliseum—plentiful in the afternoon and doubly so at night—would seem to indicate that there are many people living in Chicago and vicinity who have the desire to own, and not the price with which to buy, an automobile. The same percentage of the attendance at other shows may exist, but the patrons of the Chicago exhibition include not a few who wander about the aisles with small thought of possessing a car except in the indefinite future. Some day the "poor man's automobile" may become a reality, and if the non-buying thousands tell the story of the interest of the masses in the motor-driven vehicle there will be many to buy this car when its indefinite appearance becomes an actuality. Just now the makers have their work cut out for them in supplying the growing demands of those who are able to purchase in the period that will precede general standardization and a consequent decrease in the cost of production.

PARTICULARLY WELL DONE ARE THE AUTO SCENES THAT ARE HUNG ABOUT THE COLISEUM—"NO. 9" IS TRACY CUP "LOCO."

THE MERGING OF THE TWO SHOWS IN ONE

By CHAS. B. HAYWARD.

CHICAGO, Feb. 5.—It is with some foundation in fact that Chicago has for the past three years claimed to have the only national automobile show held in this country, for it will be apparent on a little study of the subject to see that the annual event held in the Windy City is the only one that is truly representative of the American industry as a whole. Since the separation of the trade, so sharply emphasized by the holding of two distinct New York shows on different dates and in different buildings, it must be conceded that he who would see the industry housed under the same roof—or two of them, as no one has been found large enough—must come to Chicago. Chicago's show is truly national and Chicago glories in that fact. Nowhere else is there ever brought together at the same time such an infinite range of motor-driven vehicles. Here the Automobile is typified by every form of self-moving car. Here it is that indigenous product, the aptly named "Buggyabout," is at home. It is a true native, and it is one of those things that well exemplifies the saying that necessity is the mother of invention. This is a country of roads that are such in name only. Here the famous gumbo is to be found in all its glory, and the car that will continue to make progress when hub deep in this most tenacious of muds is indeed something that requires to be particularly designed with the quality of "get there" written large in its make-up.

The Buggyabout Very Prominent.

Never in the history of the industry has there been so much evidence of the combined effort that is bending toward that long sought for culmination, the "poor man's automobile." Minus its equine power that has for centuries past been its only means of locomotion, the buggy stands forth in essentially the same form that it has always preserved; high wheeled, box-bodied, and leather topped it is the same old buggy of our forefathers. But

beneath its shining black varnish and under its upholstered seat, it has been endowed with new and unseen, but not unheard, vitals—the internal combustion motor, usually of the two-cylinder opposed type. This, with a chain, rope or friction type of drive combines to make a power plan that is indeed simplicity in itself. Its driver finds need of scarcely more knowledge than that he required to look after the wants of "Old Dobbin." Like that time honored and uncomplained friend of humanity, the aid of the modern farmer is subject at times to sudden decease, but unlike its predecessor, there is seldom any need of holding obsequies, for with the widely spreading knowledge of the make-up of the gasoline motor, in the handling of which many a tiller of the soil is a past-master, the highwheeler occasionally gives out, but never dies.

The persistency with which a now well known Chicago firm has adhered to the manufacture of this type of vehicle during a number of years, despite that keenest of weapons, ridicule, showing what it could do, has brought home to a rapidly growing number of manufacturers for the first time, the possibilities and the promise which this truly American creation holds for the future. Here it is represented in the shape of the output of a number of manufacturers who are publicly uncovering their productions in the Coliseum and the Armory for the first time.

All Under the Same Roof.

To the blasé show-goer, not to mention that very large and constantly growing section of the automobile wise public, the national show which is an event long anticipated by the population of the Middle West, offers an opportunity to see what is being done in every factory in the land. Literally, of course, the cars are under two roofs, for even Chicago, accustomed as it is to doing big things, has not found time to provide one building that

would begin to house all those more than willing to pay for space. But, figuratively speaking, they are all sheltered by the same roof, for a trip through the aptly named "pneumonia alley" brings the visitor from one land of enchantment to another. At first he is scarcely able to believe his eyes, and indeed it does seem as if he had been led around the block and taken in another door of the same show, for in both he finds the same elaborate decoration under which every square foot of bare wall and column has vanished, leaving in its place a complete picture that at once delights and rests the eye. In both of the big buildings there is the same profusion of softly glowing lights shedding their radiance over a scene that is conceded, even by the majority of those, fresh from the famous effort that transformed Madison Square Garden into fairy land, to be without a peer.

Runabouts Are Much in Evidence.

Naturally enough the cars themselves come in for attention, first, last and all the time; they are the first thing to hold the visitor's attention once he has fixed in his mind the most salient features of the engaging picture. The bright rows of auto-

When the west has developed its highways and obtained those perfect running surfaces we all dream of, and most believe will come, the open runabout may have to give way under changed conditions. For the present it is here, and here to stay.

In the Realm of the Parts and Accessory Makers.

Once he leaves the cars below and ascends to the galleries, the autoist finds himself lost in a maze of exhibits, every one of which beckons him to stop and investigate, for here, girdling the entire building is an apparently never ending succession of booths to catch the eye and hold the attention. Whether it be tires, rims, wheels, the essentials of lubrication, carburetion or ignition, speed and distance recorders, headlights to show the way, or even those very fundamentals such as steels and other materials not readily recognizable in their present form, the showing is truly a representative one. There is a wealth of parts and accessories for the most inconsequential up to those which form part and parcel of every modern automobile that is astonishing and reveals in no uncertain manner the vast extent of this secondary industry which has been developed in such a short time and is here gathered together from all parts of the country.

TWO EXPONENTS OF AIR-COOLING WHICH ARE PLACED SIDE BY SIDE—IN COLD WEATHER DEMONSTRATING THESE CARS EXCELLED.

mobiles, big and little, with their mystifying machinery and their shining varnish and polished brass, are magnets that hold interested groups as long as the show is open. Fashion has decreed that the high powered runabout shall be the queen of cars, and manufacturers, one and all, have bowed to the mandate and have vied with each other in producing two and three-seated cars embodying comfort, speed, and power. Not even the maker of the silent electrics has been proof against the mysterious influence which is felt, though not seen, and to which the sales department must ever bend the knee. That this most handy form of high speed touring car has silently but surely wormed its way deep into the affections of the autoist, must be regarded as a foregone conclusion, when the number of these very racy cars staged here is taken into consideration.

Next to these, the ingenuity that the carriage maker has displayed in devising luxury in new forms in the shape of the gliding electric for the private use of milady and in the elaborately appointed closed bodies shown on the gasoline cars, which exemplify the last note that even the most skilled of designers has been able to sound, has provided a never ending source of keen delight and interest, particularly for the fair sex. Western road conditions are largely responsible for this runabout supremacy.

MEETINGS AND SOCIAL FUNCTIONS.

CHICAGO, Feb. 5.—The week is replete with various meetings and social functions. To-day the makers of electrics held a session. To-morrow the executive committee of the National Association of Automobile Manufacturers will consider the report of the contest committee, though no action will be taken until March as to the holding of an endurance run. Thursday the American Motor Car Manufacturers' Association will hold its annual meeting, and either James Couzens will continue as chairman of the committee of management or Benjamin Briscoe will succeed to the place. Mr. Briscoe desires that Mr. Couzens shall continue, but the latter inclines to having the former take the chairmanship. Three new concerns will be admitted to membership, bringing the total up to forty-three makers of cars. The mechanical branch of the Association of Licensed Automobile Manufacturers will have one of its monthly discussions to-morrow.

At the meeting of the Electric Vehicle Makers to-day officers serving the past year were re-elected as follows: President, Colonel George Pope; vice-president, George Studebaker; secretary, Robert K. McLloyd; treasurer, M. L. Goss.

PHOTOGRAPHERS HAD DIFFICULTY IN OBTAINING GOOD GENERAL VIEWS, ONE HANDICAP BEING THE POOR LIGHT WHICH FILTERED THROUGH THE YELLOW MADE SKY.

THE WINTER JOURNEY OF A RELIANCE TRUCK.

Three hundred miles over frozen, rutty roads, and no end of snow, is the record of one of the most unassuming exhibits in the Armory. It is the Reliance truck that came into Chicago under its own power and ran to the show on its own wheels. In addition to the heavy snow already on the ground, considerable part

THE TRUCK THAT MADE THE MIDWINTER RUN.

of the trip was made through a steady snowstorm with the mercury dropping out of sight in the tube all the time. The trip was made to demonstrate the efficiency and reliability of the Gearless transmission with which the Reliance two-cylinder, two-cycle 30-horsepower truck was equipped. It is made by the Gearless Transmission Company, of Rochester, N. Y., and has been adopted as the standard equipment of the Reliance trucks.

In addition to a dead load of a ton and a half, the truck carried a live load consisting of George F. Day, sales manager of the Reliance Company; George D. Wilcox, manager of the Gearless Transmission Company, and O. W. Davis, inventor of the transmission, in addition to a supply of gasoline and lubricating oil sufficient to last the entire run of 300 miles. The actual running time for that distance was 33 hours 49 minutes, which included the time spent in replenishing the oil cups on the road each day. This means an average of nine miles an hour throughout, and

that's going some for a loaded truck under such adverse conditions. The truck is geared to make a maximum speed of 15 miles an hour, and on one road an average of 13 miles an hour was maintained for three consecutive hours.

The start was made from Detroit, Saturday, and the first stage of the run ended at Ypsilanti, Mich., at 5.45 that evening, 32 miles having been covered. Sunday was a banner day, for 7.50 in the evening, after twelve hours on the road, found the party at Coldwater, Mich., a distance of 82 miles. The day's achievement was the more remarkable owing to the fact that the entire road was a succession of grades varying from 5 to 12 per cent. Another day's run landed the expedition at South Bend, Ind., a distance of 79 miles, this part of the run being over good roads though buried under considerable snow. Had there been any necessity for it the next lap might have been made the last, but taking things easily, Hobart, Ind., a distance of 68 miles, was made just shortly after sundown that evening. The next day's run was a mere jaunt of 43 miles to Chicago, which was made in the excellent time of 3.44, the arrival being at 11.05 a. m. The car was equipped with solid tires, and to give traction sections of heavy logging chains were wrapped around the rear wheels, the only things that made progress possible through the heavy snow which was encountered throughout the trip, varying from a few inches to two feet in depth, the drifts nearly burying the front wheels altogether at one place.

Racing Cars Attract the General Public.—"That's the racer which took part in the Vanderbilt Cup race," was constantly spoken by visitors to the Locomobile, Thomas, Matheson and Haynes stands. It seemed as though everyone had heard of the big race and knew the names of the cars which participated in the American automobile derby. Around these motor warriors there was invariably a gathering of interested onlookers, even at the Apperson stand, where photographs only told the story of the company's hard luck in the practice which preceded the Elimination Trial, the views of the racer wrapped around a telegraph pole were in constant inspection. H. N. Harding, who drove the Haynes car in the Elimination Trial, was a notable figure around the Oldsmobile exhibit, for which concern he will be a speed pilot in the coming season's racing events.

SHOWN FOR THE FIRST TIME IN CHICAGO

Diamond T Motor Car Company, Chicago.—This is a new firm to enter the field of manufacturing high powered touring cars of the standard type, though its product, which is making its debut at the present shows, reveals the touch of an experienced hand, as its design combines all those features of standard practice which have come to be recognized by designers the world over as best adapted to give the service required by the exacting conditions under which the modern automobile is operated. It is a car of very attractive lines as well, and despite the fact that it is equipped with a 50-horsepower motor and is designed in keeping throughout, the weight has been kept down to the very reasonable limit of 2,800 to 2,900 pounds through the use of high-grade materials and the adoption of only the most advanced types of accessories, such for instance, as an improved form of honey-comb radiator of very light though durable construction, and which requires an exceedingly small amount of water to maintain the motor at the proper temperature.

A Simms-Bosch magneto of the high-tension type has been adopted as the source of ignition current, supplemented by a battery system using a set of accumulators and working through a dash four-unit coil, each side of the ignition system being entirely independent of the other, so that there are in reality two sources upon which to rely in a case of emergency. Transmission is by means of sliding gear with final drive by propeller shaft; semi-elliptic springs of generous proportions and of the best make form the suspension, the chassis being mounted on 36 by 4 1-2 wheels, the purchaser being given an option on tires of any standard make.

Three models are listed using the same chassis as a foundation—a special high-speed runabout at \$3,250; fully equipped touring car at \$3,500, and an attractive limousine at \$4,250. In the matter of equipment this firm has made an innovation that will be appreciated by the average purchaser. For instance, in the case of the touring car, the selling price includes a folding glass wind-shield, a pair of 9-inch Rushmore search-lights, a Jones speedometer and a cape top of best quality, the equipment of the other models being similar, in keeping with the purpose for which they are intended, so that when delivered to the buyer the car is all ready for the road, and there is no necessity to add several hundred dollars to its cost before it can be considered complete.

Marvel Motor Car Company, 284 Rivard Street, Detroit, Mich.—The \$800 Marvel runabout is making its debut here, and as it is in a class by itself its advent has been looked forward to with considerable interest. It is a typical two-seater of attractive aspect, the power plant consisting of a two-cylinder horizontal opposed engine of modern design, with a capacity of 14 horsepower at moderate speed, and has great pulling power. Like its larger compeers, it is equipped with a cone clutch and shaft drive, a two-speed and reverse planetary gear forming the intermediate step and making a sort of "foolproof" unit power plant and transmission. The wheel-base is 84 inches, tread standard, and the weight of the car in complete running order, all on, is in the neighborhood of 1,200 pounds. The wheels are 30 by 3 inches and pneumatic tires of standard makes are included in the equipment, as well as the usual outfit of side lamps and tools. The Marvel is a car of which more will undoubtedly be heard during the coming season, if not in the immediate future. Its bid for popularity is a strong one.

Chicago Coach & Carriage Company, 1223-31 Michigan Avenue, Chicago.—This firm has entered the field of automobile building by bringing out one of the increasingly popular "buggyabouts," which have formed such a prominent feature of the present show. It is called the Duer, Model A, and it embodies many wrinkles of modern automobile construction not usually found in this type of car, and not ordinarily open to the manufacturer owing to the low figure at which such cars are offered to the public. The Duer is the first of its kind to combine the regulation bonnet in front demanded by fashion with the high-wheeled and solid-tired buggy type of vehicle that is necessary for the navigation of many of these sub-aqueous western roads, which are generally a mixture of six parts water to four parts mud. On this account it has been equipped with 44-inch front and 48-inch rear wheels, fitted with side wire solid rubber tires. The wheel-base is 72 inches and the tread standard. The motor is of the two-cylinder horizontal opposed type, air-cooled, and is placed forward transversely under the bonnet; it has automatic inlet valves and every part is made readily accessible, so much so that the whole motor may be dismantled in 30 minutes.

ONE OF THE WESTERN NEWCOMERS: 40-50-H.P. DIAMOND T TOURING CAR, SHOWN FOR FIRST TIME.

MODEL "A" DUER, OF THE CHICAGO COACH AND CARRIAGE CO.

Ample exhaust piping and large valve dimensions have been used, a separate muffler being employed for each cylinder.

Motor suspension is on the well-known three-point principle. The transmission giving two speeds ahead and reverse is of a special patented type, made especially for use on this car. Directly beneath the motor there is a secondary or jack shaft running at right angles to the crankshaft. Upon this is supported the transmission connected to the motor shaft by a telescopic universal joint. The jackshaft runs on roller bearings resting on slides at each side of the car just under the sills, permitting the entire transmission unit plenty of lateral play in order to tighten or relieve the tension on the power cables. The car is steered by a side lever, and is operated entirely by a single lever, which gives all the speeds. The car lists at \$750.

Franco-American Automobile Supply Co., Chicago.—As its name indicates, this firm may most aptly be termed one of the "universal providers," for nothing of merit in the line of auto supplies, whether produced abroad or in this country, is foreign to its stock. Prominent among its imported specialties are Michelin tires and the products of the "Maison Rubay," which means, of course, La Coste ignition accessories in the shape of French coils, magnetos, timers, plugs, electric lamps and limousine fittings; the "MAB" French annular ball bearings; the "O. S." Odospeedometer and "les phares" Bleriot, this house being the first to make automobile lamps and headlights. In domestic productions, it is hard to know where to begin to enumerate the endless variety in which the necessities of the car and the autoist are handled. There are the Look ignition accumulators, "Franco" oil cans and drip pans, portable garage turntables, a novel and compact tank whistle for direct connection to the engine whether marine or automobile, "the "W. & N." ready valve remover, the Robert line of pocket meters, Kingston carbureters and other specialties made by this house; "Fite Fire" extinguishers particularly designed to be carried on the car or in the motor boat as well as for garage use; the Bell compound tire pumps and positive pressure indicators, the Monahan Antiseptic Company's "Green Oil" soap for cleaning the auto bed and running gear; the numerous specialties made by the Turner Brass Works, such as Turner bronze foot treadles. Ross fluid level indicators for tanks, Martin gasoline strainers and multiple feed lubricators, the Turner carbureter made in four sizes and a number of others. Then there are the "Never-Miss" specialties, such as Never-Miss plugs, ammeters, wire terminals and chain repair devices; the Black Hawk dry batteries and meters; the Oliver Instrument Company's "Index" speed indicators and odometers, "American" headlights,

the "Channon" repair kits and the "Amco" specialties, such as fenders, extra tire holders, long distance horns and others which are made by the Appliance Manufacturing Company of Chicago, Ill. A new line is that of the Adapt Machinery Company, in the shape of folding glass windshields in all brass frames, auto bumpers, tire irons, chain tools, mechanical oilers, brass and iron auto trimmings of every kind and general auto machine work, this firm having special facilities for this class of operations. Other specialties are the Woodworth detachable treads made by the Leather Tire Goods Company, the "Auto-Cle" handy socket wrenches and Stanwood steps; "E. & J." headlights and lamps made by Edmunds & Jones Manufacturing Company, of Detroit; the Hotchkiss "anti-jolt" device, which is the invention of P. M. Hotchkiss, of this city; "rapid" wrenches and "Westbrook" acetylene gas generators made by the E. T. Kimball Company, Boston, Mass.; the Kilgore Shock Eliminator made by the Kilgore Auto Air Cushion Company, also of Boston, "U. S." Jacks; Cox repair kits; "Stop One Minute" tire adjusters; "Helmet" and "Primus" motor oils; Wiley tire and lamp covers; Charter spark plugs, and numerous others, for many of which this company has the exclusive agency, and of others the entire western territory.

Stewart & Clark Mfg. Company, Chicago.—The Stewart Speedometer is a product of the home soil that made its debut at the Garden last month, where it aroused no little interest, and is now being publicly exhibited in its own birthplace for the first time. Realizing the curiosity of the public to see the "works" hidden by the compact, polished brass case, the manufacturers of the Stewart have taken advantage of it to reveal the small number of parts that constitute the mechanism of their instruments, and have placed them on display in show cases in their booth in the Annex. In addition to this, two of them are also shown in operation under conditions approaching as closely as possible to the use under which they run when on the car. They are mounted on a dashboard, and are run through the regulation flexible shaft and gearing from a standard automobile wheel. Two styles are shown, one calibrated to read up to 60 miles an hour, and the other up to 120 miles. The instrument is based on the principle of centrifugal force, and has been designed particularly with a view to giving what is known as a "dead-beat" reading; in other words, the pointer remains steady at all speeds, and does not jump or vibrate back and forth. All parts are designed of generous proportions and are well finished. The trip and season mileage are shown on a Veeder Odometer. They are also showing the "Long Distance" Siren—the auto signal that is different, and that never fails to clear the road ahead.

ARTISTIC OLD ENGLISH MAIL COACH BODY FITTED TO APPERSON.

London Auto Supply Company, Chicago.—"Lasco" glass fronts are being specialized by this firm. They are of the folding type, and are characterized by a degree of neatness and simplicity that is a relief to those autoists who can recall their struggles with the old-time glass wind shields. The folding feature, and the ease with which adjustments can be made merely by loosening two generously proportioned wing nuts, or thumb screws, is a strong recommendation, for the solid glass shield often becomes a menace to the driver in wet or muggy weather, and removing it entirely results in undue exposure. The "Lasco" fronts are made of 3-16-inch clear plate especially selected for this purpose and measure 25 by 39 inches, folding at the center. Over all the dimensions are 32 by 42 inches, the frames being hardwood finely finished in black, oak or mahogany, trimmed all around with heavy brass binding. The hinges, stay rods and other trimmings are of solid polished brass.

the recoil so that no matter how hard the bump the passengers are not thrown off their seats. It is very easy to attach and requires no oiling or adjustment when once in place on the car. The price per set of four is \$60. This firm also shows the McKinney removable tire holder and the Baldwin block and roller auto and machinery chains, as well as a line for cycles and motorcycles.

McCord & Co., Old Colony Building, Chicago.—In addition to the McCord force feed lubricator, to which this firm has so long devoted its attention with the result that it is a part of the standard equipment of many of the best known makes of cars, they are now turning out a line of carbureters that bid fair to come in for the same extent of favorable consideration that has been shown their predecessors in the lubricator field. Beside this, they are manufacturing radiators as well as the McKim copper-asbestos gaskets.

A GENERAL VIEW IN THE FIRST REGIMENT ARMORY, WHERE MANY PROMINENT CONCERNS ARE HOLDING FORTH COMFORTABLY.

Bethlehem Steel Company, South Bethlehem, Pa.—The exhibit of this firm is one of great interest to the engineer in that it shows what can be accomplished by the science of metallurgy as applied to the improvement of the component parts of the automobile. Mounted on a plate are shown five pieces representing the various stages through which a drop-forged crankshaft must pass in its transformation from a square rod of steel to the finely finished piece of work ready for the assembler. A large number of drop-forged parts for various other purposes are also shown, as well as test pieces of steel, one in particular of a connecting rod which has been twisted several turns and then given a 180-degree bend flat upon itself. This is a cold bending test such as has only been made possible by scientific heat treatment of the metal during the processes of manufacture.

Baldwin Chain & Manufacturing Company, Worcester, Mass.—One of the chief features of the exhibit of this concern is the 1907 model of the Baldwin Spring Recoil Check, which is designed to permit free compression of the springs under any conditions of running, but which gradually absorbs

A Fine Line of Distance and Speed Recorders.—It is putting it mildly to say that the line of distance and speed recorders uncovered by the Auto Improvement Company, an offshoot of the American Electrical Novelty Company, 16 Hudson Street, New York, forms one of the sensations of the show where these instruments are concerned. This firm has taken advantage of the demand that has long been apparent for an instrument to suit the needs of the tourist whose car seldom reaches or exceeds 40 miles an hour. To such autoists the speed range from 50 to 75 miles is a useless superfluity that must nevertheless be paid for. They have accordingly brought out the "Ever Ready Tourometer" with a speed range from zero to 50 miles an hour, combining with it a trip odometer reading to 999 miles and repeat, and a season mileage recorder to 9,999 miles. The case is of solid bronze and is dust and waterproof, the dial being of aluminum with black figures, making it easily readable at a distance. The gears, flexible shafting and mechanism are the same as on the expensive instruments. Complete it sells for \$35.

Its next larger brother is the "Ever Ready Roadster" and reads to 65 miles. The instrument is much larger and both the trip and season odometers run to 9,999 miles before repeating. This is a

YARDS OF RED AND WHITE BUNTING HANG FROM THE GIRDERS, AND FLAGS GIVE A PATRIOTIC TINGE TO THE DECORATIONS.

ACCESSORIES FIRMS WERE WELL PLACED IN THE GALLERY OF THE COLISEUM AND HAD LIGHT AND VENTILATION.

racing model, particular pains being taken to make it accurate at all speeds and it will be calibrated up to 135 miles per hour if desired. The odometer indications are recorded by a new principle, the index showing on plain engraved rollers in black numbers, with fractions in red. Every revolution of the wheel is recorded whether going ahead or backing. Complete with gears, brackets and flexible shafting, the "Roadster" sells at \$50.

For the autoist who wishes to limit the number of ornaments on the dash of his car, there is the "Ever Ready Universal" or "all in one" model. This is the same instrument as the "Roadster" with the addition of a clock, though the complete combination is scarcely larger than its compeers who are without this valuable feature. This is a combined speed, distance and time recorder par excellence. Complete it sells at \$60.

Another noticeable specialty offered by these makers is the "Ever Ready" Standard Vulcanizer. It is a complete tire repairing plant in a compact, self-contained form. Equipped with a combination of tools, each particularly designed for a special purpose, it is fitted to repair shoes and inner tubes, blow-outs, rim cuts and retreading or make good any damage to canvas or rubber. Punctures, blow-outs and reseating valves are also naturally within its province. Besides this there is the "Ever Ready" car vulcanizer and the "Ever Ready" tire tool which are specialties made by this firm.

Limousine Carriage Manufacturing Company, Chicago.—The Schildback and Beecher divided wind shields are the specialties manufactured by this firm, upon which they lay special stress in their exhibit. A patent has been applied for on the former, its construction being such as to entirely do away with hinges, which constitute one of the most annoying features of the ordinary style of shield. In this new form, the upper half is held perpendicular to the lower by a tapered pin fitting into a corresponding recess in the top of the lower half and is further stiffened by a brace running from a slide on the lower rigid brace. The upper half is lowered by loosening two set-screws and has the great advantage of coming down parallel with the lower half, thus making it easy to use no matter how close it may be to the steering wheel. Beside this, in lowering it, the top of the upper shield comes down level with the top of the lower side, which is an unusually attractive feature, as regardless of the position of the shield, the appearance it makes on the car and the view of the driver remains the same. The bolts turning in the slides running on the forward braces are fitted with long nuts with wheels on their ends, working the same as a loose washer, thus allowing the upper frame to be held at any angle of the circle, which has the advantage of permitting the shield to be lowered just sufficient to clear the dash lamps.

Hancock Manufacturing Company, 144 East Erie Street, Chicago.—Under the head of "Points Worth Noticing," the makers of the Hancock "Valveless" oiler call attention to the many things in which their system of oiling is designed to give satisfaction to the autoist by its simplicity and reliability. It is so much a matter of common knowledge even to the mechanically uninitiated that bearings, slides and all other moving parts, whether small or large, and they must of necessity be small in an oiler, are things that require constant attention to keep them working properly. Otherwise there is going to be trouble—hence, the "valvelessness" of the Hancock, and hence its advantages, of which this is the chief. Supplying lubricating oil on the "feast and famine" principle is what sends so much valuable machinery to the scrap heap in such a remarkably short time, and nothing sooner than a high speed auto motor; oil must be fed faster as the speed increases, and stop when the motor does, otherwise there is a lack of lubrication and a waste of oil, or, incidentally, a needlessly smoky exhaust.

Acetyvone Company, 38 Park Row, New York.—One of the greatest difficulties encountered in the generation of acetylene gas, particularly on the small scale necessary on a car, is that of after generation. It is next to impossible to shut the generator off, it continues to make gas whether the lamps are burning or not, once the water has been turned on. This causes a large accumulation of gas with the risk of explosion or wastes the carbide, as a new charge is necessary every time the lamps are required. To overcome this the Acetyvone Company has brought out a special stick carbide made by a secret process which is used in an ingenious generator. These sticks are about one inch in diameter by four inches long and fit into sockets in which they slide freely, the size of the generator being increased by adding to the number of sockets, the types now being their moving around from the jolting of the car. The lower part of the generator is filled with water to a certain line, and is prevented from splashing by a series of baffle plates. Into this water the sticks dip at their lower extremities and feed by gravity, the retaining sockets and adjustments preventing their moving around from the jolting of the car. The lower ends of these sockets or tubes may be instantly closed by moving a small lever on the top of the generator, which raises a plate carrying a rubber gasket, thus hermetically sealing the seak in the containing tube and preventing any after generation. The device on the whole is so simple that the manufacturer's only caution is, "Keep it clean," and this is easy, as there are so few parts. Probably its greatest advantage lies in the fact that the special stick carbide is not so susceptible to moisture as the ordinary carbide, though its affinity for water has not been impaired by the process it undergoes in manufacture.

National Oil Pump & Tank Company, Dayton, O.—The problem of the safe handling of gasoline for whatever purpose this inflammable fluid may be used has been made a study by this concern, and they have evolved a line of convenient apparatus for the autoist as well as for the garage-keeper, regardless of how much or how little fuel he is permitted to keep on his premises. Their lines consist in the main of the National self-measuring, registering and computing tank outfits and long distance storage outfits in all capacities. The pumps are of the combined suction and force type, built entirely of brass, steel and malleable steel castings. They are equipped with hand-ground anti-drip discharge cocks and lever shut-offs, absolutely preventing any loss from evaporation, while the discharge register tallies the gallons and half gallons exactly as pumped. Every pump is equipped with a special locking device embodied in the casing, only the key post being visible. They also specialize on outdoor cabinets, fire-proof cabinets, runabout tanks, and other forms of metal reservoirs.

Wray Pump & Register Company, Rochester, N. Y.—This firm has recently branched out into another line than that of making pumps and pressure indicators, for which they always have been known, by undertaking the manufacture of the Lindsay timer and distributor, a device which has many claims to merit. It is designed to be attached to the dash and is protected by a bell glass covering which permits of its operation being readily followed at all times. The battery wire enters from beneath, passing through a bridge support, and is connected to an adjustable spring plunger, making a wipe contact on the arms of a starwheel; at the same time the secondary current enters at the right through a similar connection and makes contact with a bronze ring recessed on the under side of a fiber turntable carrying the starwheel.

(Continued on page 297)

THE SHOW FROM VARIOUS STANDPOINTS

Fisk Rubber Company, Chicopee Falls, Mass.—It is evident that the men who make the Fisk tires have not been sleeping where the matter of dismountable rims is concerned, and they have brought their surprise with them to the Windy City. It is something that makes a man who thinks he knows all about dismountable rims open his eyes and take a second look and then ask to see the works. There are the usual nuts visible that have always characterized the form of mechanically fastened tire to which this house has so long and consistently devoted its energies, but the sophisticated tire user begins to marvel when he sees that these are not to be removed as usual. The demonstrator gives them a twist or two and, without going further, proceeds to lift the tire from the rim. This is where the surprise comes in, and unless the looker-on is familiar with mechanics, the very simplicity of the device is what most puzzles him. He cannot see just what keeps the tire on or what permits it to come off again,

AN ATTRACTIVE CORNER IN PACKARDS.

though there is no doubt in his mind that it is there to stay when he tries to move it after the nut has been tightened. Its secret lies in the employment of a simple split ring with a beveled inner face in contact with a similar face on the rim proper. When the nuts are tightened the face of the ring is forced to slide on that of the rim, and in consequence it rises vertically, thus gripping the tire at its strongest point with a hold that nothing should be able to shake loose.

A Bay Window Limousine.—As in Gotham, the Isotta Fraschini "bridal car" was the cynosure of all eyes, and in addition the Hamilton Automobile Company's showing of imported cars included a very novel and attractive body by Kimball, which was rather out of the ordinary. In place of the conventional side windows they were given a slight bow, somewhat on the order of a bay window, enabling the passengers to see ahead. Every convenience and comfort that the art and ingenuity of the carriage builder could suggest was incorporated in its interior furnishing, including adjustable footrests, extra folding seats that disappeared in the side of the car when not wanted, and a multitude of other small luxuries that are now considered a necessary part of the interior finish of the up-to-date car. Small bevel plate glass mirrors mounted in polished frames are also set on the front stanchions of the hood to enable the driver to see to the rear when running under crowded traffic conditions.

Mr. Hotchkin's Teddy Bear Attracts Notice.—Probably the most congested part of the entire show was to be found at a point on one of the aisles in the Coliseum Annex. There was always an interested crowd there, and the casual visitor found it difficult to get near enough to find out what the center of attraction consisted of. When he finally did succeed in worming his way through, if he did not get an inkling of what was going on by seeing a monster Teddy Bear mount ceilingward over the heads of the spectators before he got within the charmed circle, a sight of one of the cleverest exhibition "stunts" ever put on to show the merits of a shock absorbing device rewarded his efforts. P. M. Hotchkin, maker of the well-known Hotchkin "anti-jolt" device, conceived the idea of showing in a simple and impressive manner just how his invention really does away with the shocks and jars instead of merely absorbing them. He has rigged up a seat after the fashion of one of the bucket seats of an

AN "INDEPENDENT" WHO WAS WELL PLACED.

auto, mounted on springs of the regulation type, and devised in such a manner that the occupant may receive the benefit of the anti-jolt device or not as the demonstrator wishes. The springs are compressed by means of a long lever, and when the anti-jolt is "not on the job," as some of the admiring gamins expressed it, the bear soars the moment they are released, and falls back with a thud, sometimes losing his passage altogether by being thrown out of his seat, which would often be the case with the passengers in a car were it not for the high sides of the tonneau. Then the operator compresses the springs till they almost touch, and suddenly releases them with the device working; the result is a slow, easy and almost imperceptible reaction, which brings Mr. Bear up comfortably without in the least disturbing his equilibrium or unsettling his center of gravity. "In one case he never knew what struck him, and in the second, he never knew it happened," as an amused spectator put it. Mr. Hotchkin's bear is certainly the "sight of the show."

Frank P. Illsley, Chicago, Stevens-Duryea Agent, was a thoughtful man in providing fur coats and caps for those who sought demonstration rides in the big and little "Sixes." Autoing in typical Chicago weather, such as seems to be on tap this week, is far from comfortable, and a warm-clad man is a more probable customer than one half frozen. Doubtless Mr. Illsley has reaped the reward of his thoughtfulness.

WHERE THE BIG AND LITTLE "SIXES" WERE SHOWN.

THE NEW PEERLESS OF DESIGNER SCHMIDT.

Edgar Apperson on Long-Distance Racing.—It will be remembered that the Apperson Brothers built a fast car for the American Elimination Trial of the Vanderbilt Cup. In the preliminary practice, driven by George Robertson, the car showed most encouraging speed, but one morning a flat tire brought about the accident which temporarily ended the career of the Apperson candidate. Commenting upon the worth of automobile competition, Edgar Apperson expressed himself in this vein: "If the Racing Board of the A. A. A. established a long-distance contest of anywhere from 700 to 1,000 miles, calling for stock chassis, we would certainly be an entrant. Undoubtedly it would be necessary to occupy two or more days, place the cars in the hands of the Racing Board at night, and only permit the driver and his mechanic to work on them, and then during the hours of the race itself. In order to make positive that stock chassis only would be used, it might be necessary for the Racing Board to send a representative to the factories of the entrants and there stamp in such manner as to make substitution impossible the chassis to be used in the race. It would seem to me that 2,500 pounds would be a fair weight limit for the chassis, which, of course, would be something in excess of a present total weight of 2,204 pounds for the machine as it comes to that starting line. It is my belief that a race of this character would be beneficial to all concerned, and I am not sure but that a limit might be placed on the total piston displacement, giving the builder the option of distributing the cubic inches in as many cylinders as he might desire."

An Old English Mail Coach.—Speaking of bodies there was nothing that quite equalled in attractiveness the old English mail coach body shown on an Apperson chassis by the Kimball Company. With its quaint round lines and old-fashioned coloring it was a novelty such as has seldom been seen on pneumatic tires. Every detail of the old-time conveyance, so oddly named a "Diligence," and one so familiar a sight on English roads, has been reproduced here, and all the lines of the ancient and of the most modern vehicle have been blended artistically into a harmonious entity that is a delight to the eye. With its small square panes in the windows of the coach and its old-time booths behind, it is the typical application of the standard of the Eighteenth century to the form of locomotion of the Twentieth.

A New High-Tension Magneto.—Some of the ignition wise found something to interest them after having made the rounds and taken a close look at the cars. "That's a brand new magneto. I haven't seen that one before. Wonder who makes it? It certainly looks good." Investigation showed it to be the product of the Splitdorf Laboratory in the shape of a high-tension magneto on the Triumph car, and it has also been decided upon as a part of the standard equipment of the Thomas among others. It is the result of several years' hard study and extended tests on the part of a man who has made the building of electrical apparatus a life study, so that he knows it is right.

A PIONEER THAT HOLDS ITS OWN.

WAYNES AND STUDEBAKERS WERE NEIGHBORS.

THE BIG STEARN'S AND TWO-CYCLE ELMORE.

A Reminiscence of the Vanderbilt.—Merely for the asking, the visitor could obtain a section of the Vanderbilt race at the Pantasote booth, and in a form to mail to his friends to show just how the race looked when he was there. It takes the form of a post card to which is attached a moving picture annex depicting Lancia and his Fiat flight around Krug's corner when it was merely a matter of fractions of a minute whether he or Wagner would cross the line first in the matter of elapsed time.

A Novel Advertising Stunt.—No matter where the spectator looked he saw "Fisk Tires Carry All." At very turn and on every hand, or, more properly speaking, in every hand, for the Fisk publicity creator had taken heed of the philosophers and made it his business to make others work

for him and spread the tidings of Fisk tires broadcast. Every man, woman and boy of the genus catalogue fiend carried Fisk tires—not the tires themselves—something that told the tale quicker—a Fisk carryall into which to shove the gathering of many a round of the car and accessory stands in both the buildings.

Pardee & Canary, 1218 Michigan Avenue, Chicago, have just taken on the agency for the well-known Renault cars, as representatives of Paul Lacroix, of the Renault Frères Selling Agency, New York, and are making an attractive exhibit of the line in the First Regiment Armory, where all the imported cars are housed for the week. In connection with their other agencies, which include that of the American Mors, the American, Babcock electrics, and others, this firm has an unusually complete showing.

The Ford Fire.—Fire unceremoniously brought the Ford Motor Company's private exhibit, which was being held at the local agency at 1444 Michigan avenue, to a sudden and unpremeditated close but a few hours after midnight of Sunday. But almost before the fire department was through its work cooling the ruins that represented about \$50,000 worth of new Fords, both of the six and four-cylinder types, which had gone up in smoke, Manager Hay had made his plans to continue the show. He at once engaged new quarters in the furniture exposition building at Fourteenth street and Wabash avenue and rushed the cars that had been saved from the fire around to the new address, at the same time wiring the factory to forward all that could be spared by express. The doors were opened on the new agency rooms and the show at noon to-day. Immediately upon learning of the fire, Ralph Temple, president of the Automobile Dealers' Association, offered Mr. Hay the use of half his establishment at 309 Michigan avenue, but the latter thought it best to obtain the Wabash-avenue quarters.

AN OFT-ASKED QUESTION WHICH ELICITS MANY ANSWERS, MANY OF WHICH MIGHT BE CORRECT.—McCutcheon in *Chicago Sunday Tribune*.

IMPORTANCE OF STRENGTH IN SIDE FRAMES

By THOS. J. PAY, E. E.

OF these important members in automobiles, while much has been said, there is yet some room for discussion, particularly in view of the decided tendency to resort to the use of alloy steel on account of its great strength and consequent rigidity. While it is true the strength of alloy steel is very great in comparison with sheet steel, as ordinarily procurable upon the open market, even so, the fact remains that the finer grades of flange

FIG. 1.—C-46-O Krupp steel chassis frame cross member. Closed on itself without showing cracks. Under shock test this steel deformed 3.03" after the fifth blow under standard conditions and the "proof" was then bent double, without showing cracks.

steel are worthy of serious consideration, possessing as they do not only a fairly satisfactory tensile value, but other desirable properties to a marked extent. Alloy steel, on the other hand, possesses the highest tensile values, but its performance in some respects may not be so good, and what is gained in one way may be lost in another; hence to discuss the matter, with a view to clearing up some of these points, will be the main object here.

Mild Steel Not a Suitable Material.

From time to time, as opportunity afforded, the writer has tried out, in actual service, chassis frame members of mild steel, specification flange steel and chrome nickel steel, but in fairness to nickel steel it may be proper to say this product has been given no trial such as would lead to any adequate conclusion. Of mild steel, such as the market readily affords, it must be confessed it is a product of no good promise, nor can its use be recommended, primarily because it "wilts" on small provocation, and, again, because in flanging this product develops cracks all along the turned edges. True, the cracks are not always so well defined as to be readily noticeable, but, as a rule, the imperfections developed by flanging are easily seen through a 20-to-1 magnifying glass. There is no reason why mild steel could not be made to flange perfectly flat; reference is here made to the products usually found upon the open market—products indeed that positively will not stand bending 180 degrees and flattening down, nor will such products, as a rule, stand wrapping around a mandrel of even a diameter of double the thickness of the sheets.

Of course, by flanging "hot" it is sometimes possible to avoid the surface imperfections complained of, but not always, for in some cases the metal in question behaves badly when heated, and it is feared the commercial product usually obtainable is so inferior in its composition as to render it unsafe for use, hot or cold flanged, on the ground that imperfections are likely to develop during the flanging operations, no matter how the operation may be conducted. In any case, such products are not strong, and if chassis frame members are to be light they must be of steel, of a grade affording strength in excess of that likely to

obtain in inferior grades of steel plate, such as may be good enough for many ordinary purposes, and for which the ordinary commercial product is carried in stock by steel vendors.

It is no impropriety to manufacture and sell such steel; moreover it is very low priced, and, besides, it is absolutely good for the many uses to which it is put, outside of automobile work, but a light machinery platform, such as the chassis frame of a motor car happens to be, can scarcely serve under the usual road conditions, and prove rigid enough for the work, unless in a very light car, as a runabout within 1,000 pounds, holding a motor of very low power, and a single chain drive, by means of which the ills resulting from a chassis frame of no great rigidity would be negligible in any case.

Steel of this character, as the following analysis will show, is far from pure, and can lay no claim to quality at all. Chemical composition of ordinary sheet steel, sometimes used for chassis frames:

Carbon	Silicon	Sulphur	Phosphorus	Manganese
.20 to .30	.18 to .28	.06 to .08	.08 to .10	.40 to .50

giving the range of each component in per cent. As will be observed, the sulphur and phosphorus components are very high in both cases, and since sulphur renders steel "hot short," this product would prove troublesome if flanged hot, whereas, on the other hand, the high phosphorus component would not interfere with cold pressing, because phosphorus renders steel "cold short."

Tests Do Not Reveal Weakness of Such Material.

Any conventional physical test for tensile strength, elastic limit, elongation, or reduction of area, likely to be made, would scarcely prove the real lack of value in motor car work of this product, because the physical properties as usually taken do not show the ills of sulphur and phosphorus, although the elongation might develop a value low enough to put the steel under suspicion. The best and quickest way to illustrate the inferiority of such steel is to subject a "proof" to a 180 degrees bending test, around a mandrel equal to the thickness of the "proof," and if cracks show up no further effort to show lack of desired qualities will be necessary. Much space could be taken by way of explaining the ills likely to follow the use of any such steel in chassis frames, but most autoists of any experience at all have come across "wilted" and deformed side members, while a goodly number of autoists have had to pay dearly for the right to use this steel. Considering carbon steel further is to take up with flange steel or boiler plates, of which, to be sure, there are several

FIG. 2.—C-46-O Krupp chassis frame steel deformed to show extent of bending without showing cracks. Under a compression test this steel showed set when subjected to 85,296 pounds per square inch.

FIG. 3.—C-46-O Krupp steel chassis frame cross member. Flattened down under the hammer with no sign of cracking.

grades, but the most inferior grades of boiler plates are vastly superior to the commercial steel plate, previously referred to, and for the matter of that, "structural steel," as rolled into shapes, is a superior product in comparison.

The characteristics and composition of the products of these classes that can be obtained will be set down below for comparison and discussion.

Structural Steel—Acid Open Hearth.—Chemical composition:

Carbon	Silicon	Sulphur	Phosphorus	Manganese
.20	.20	.06	.08	.40

Physical properties:

T. S.	Y. P.	El.-8°	Cold Bend
50,000 to 60,000	30,000	26%	180° flat on itself

Structural Steel—Basic Open Hearth.—Chemical composition:

Carbon	Silicon	Sulphur	Phosphorus	Manganese
.20	.20	.06	.06	.40

Physical properties:

T. S.	Y. P.	El.-8°	Cold Bend
52,000 to 62,000	32,000	25%	180° flat on itself

Both of the above products, while much finer than ordinary steel plate, are by a considerable margin below boiler plate in real qualities.

Boiler Plate—Open Hearth.—Chemical composition:

Carbon	Silicon	Sulphur	Phosphorus	Manganese
.20	.15	.05	.06	.30 to .60

Physical properties:

T. S.	Y. P.	El.-8°	Cold Bend
55,000 to 65,000	33,000	25%	180° flat on itself without sign of fracture.

Fire Box Steel—Open Hearth.—Chemical composition:

Carbon	Silicon	Sulphur	Phosphorus	Manganese
.20	.18	.04	.04	.30 to .50

This chemical composition is very much better than any previously recorded.

Physical properties:

T. S.	Y. P.	El.-8°	Cold Bend Test
52,000 to 62,000	32,000	26%	180° flat on itself

While the physical properties are somewhat different for fire-box steel than for boiler plate, yet even so the lower phosphorus and sulphur marks this steel as vastly to be preferred for chassis frame members because of the decidedly more reliable qualities of the steel, especially in the flanging process, and as a result of flanging, even not taking into account the superior ability of this steel to withstand shock loads.

Splice Bar Steel—Open Hearth or Bessemer.—Chemical composition:

Carbon	Silicon	Sulphur	Phosphorus	Manganese
.15	.18	.08	.10	.30 to .60

This is an analysis of a strictly inferior product.

Physical properties:

T. S.	Y. P.	El.	Cold Bend Test
54,000 to 64,000	32,000	25	180° flat on itself without fracture.

This product, as a general rule, fails on the cold bending test, and, on the whole, it may be said this steel is scarcely better than the product readily afforded on the open market.

Rivet steel is rather attractive for use in what might be termed a medium good chassis frame stock, the qualities of which could be set down as follows:

Rivet Steel—Acid Open Hearth.—Chemical composition:

Carbon	Silicon	Sulphur	Phosphorus	Manganese
.08	.06	.06	.06	.80

Physical properties:

T. S.	Y. P.	El.-8°	Cold Bend Test
56,000 to 62,720	35,000	25%	180° flat on itself, both hot and cold, without cracking.

The basic open hearth steel of this grade would have the phosphorus down to .04 instead of .06 as above, considering steel as usually manufactured.

The carbon steel thus far taken into account is all such as would stand a cold bending test of the maximum desired, but these products are not of what would be called great strength. A carbon steel product to show great strength might properly be termed spring steel, a grade of which is as follows:

Spring Steel.—Chemical composition:

Carbon	Silicon	Sulphur	Phosphorus	Manganese
.50	.12	.035	.035	.80

Physical properties—normal.

T. S.	Y. P.	El.-8°	Cold Bending Test
100,000 to 110,000	40,000	23%	45° around mandrel equal to thickness of plate, hot and cold, with no sign of cracks.

This steel would, of course, be quite rigid, and should serve for chassis frames quite well, but the danger of damaging the micro-structure during the heating process would be something to take into account, and, besides, the plates would have to be annealed after bending to render them reliable.

Characteristics of Some Alloy Steels.

So much for carbon steel, unless to testify to the effect that "fire-box steel" has been used in some of the best "American cars" with entire satisfaction, will be of benefit in clearing up the whole situation. Of the alloy steel products, nickel steel and chrome nickel steel are about all that have been given a trial at length, and of these genera of steel, the writer's experience has been almost wholly confined to chrome nickel steel.

Of chrome nickel steel, one brand used by the writer for chassis frame members holds in its chemical composition the following:

Chromium	Nickel	Carbon	Silicon	Sulphur	Phosphorus	Manganese
1.40	3.30	.31	.20	.028	.012	.41

showing very low phosphorus and other evidences of fine quality. This steel in normal bars—not rolled into plates—generally tests about as follows:

Physical properties—normal.

T. S.	Y. P.	El.-2°	Con.
110,000 to 120,000	90,000 to 100,000	24%	42%

FIG. 4.—C-46-O Krupp steel chassis frame cross member. Test by hydraulic pressure on a ring showed 33.5% widening without sign of physical imperfections.

On the cold bending test, using plates 4 mm. thick, they usually will bend 180 degrees on a mandrel of a diameter equal to the plate thickness without showing cracks, but the plates will not, as a rule, stand 180° and flattening down. This product, when rolled into plates 4 mm. thick, is of very great strength, especially after undergoing heat treatment; indeed, the test, as follows, is a very reasonable expectation:

Physical properties—treated.

T. S.	Y. P.	El.-2°	Con.
150,000 to 160,000	128,000 to 135,000	16%	38%

This material was introduced in the chassis frame of the B-L-M racing car, and is regularly employed in B-L-M touring cars at the present time. It is also being put into the new Ellsworth cars, as the regular chassis frame product. There is still another grade of chrome nickel steel, differing in chemical composition, that has not been regularly adopted for chassis frame work, although it should serve quite well, the composition being as follows:

Chemical composition:

Chromium	Nickel	Carbon	Silicon	Sulphur	Phosphorus	Manganese
4.41	1.60	.25	.20	.013	.012	.35

This product is especially low in sulphur and phosphorus, and runs high in nickel and chromium.

FIG. 5.—C-46-O Krupp steel chassis frame cross member. Physical properties: T. S., 114,645; E. L., 93,167; Ex-2°, 17%; cold bending test, 180° and flatten down without sign of fracture.

Physical properties—normal.

T. S.	Y. P.	El.-2°	Con.
123,000 to 130,000	118,000 to 112,000	28%	64%

and when treated the reasonable expectation might be put down as follows:

Physical properties—treated.

T. S.	Y. P.	El.-2°	Con.
180,000 to 190,000	155,000 to 165,000	14%	48%

In flanging, this metal in the normal state will stand 180° and hammering down flat with no sign of fracture. The only reason for not using it is the fact that it is difficult to procure, excepting in round bars, whereas for chassis frames it is wanted in flat sheets about 3-16-inch thick, 9 inches wide and 12 feet long. It will be noted that alloy steel is far more pure than carbon steel, and it is due in a large measure to low sulphur and phosphorus that alloy steel performs so much better under shock loads. On the other hand, the pressure of chromium with nickel accounts not only for the great increase in tensile strength, but the near approach of the elastic limit to the tensile strength.

Tests of Some Foreign Alloy Steels.

In France, nickel steel for structural shapes as chassis frames may be had with very high nickel and extraordinary strength. One grade has nickel between 10 and 12 per cent. with physical properties as follows:

T. S.	Y. P.	El.-2°	Con.
100,000	114,000	12%

This shows by the comparatively low elastic limit, the absence of chromium; but the high tensile strength would, of course, afford great initial rigidity.

Another French nickel-steel product for chassis frames with 3 1-2 per cent. nickel, tests as follows:

T. S.	Y. P.	El.-2°	Con.
71,000	50,000	28%

This product should prove quite reliable for light-weight cars, but it does not compare with chrome nickel steel.

The illustrations are reproduced to show the extent to which fine grades of steel can be deformed, without showing signs of fracture, and it is believed side frame stock, to be thoroughly good, should be capable of withstanding the 180° bending test.

NITROGEN FOR TIRE INFLATION.

FROM THE ENGLISH MECHANIC.

It has probably not occurred to many users of pneumatic tires that some of the trouble experienced in their use could be obviated if some other elastic fluid were substituted for atmospheric air in their inflation. Of course, experiments have been made with carbonic acid gas stored in the liquid state, and with engine exhaust products collected in a storage tank; but the object of these experiments was rather to reduce the labor of inflation than to improve the action of the elastic fluid in the tires. There is no very great difference between the degree of elasticity of the different gases, and no appreciable advantage is likely to be realized in this respect; but there are two other properties of gases which affect their suitability for use in pneumatic tires, namely, their penetration and their chemical or erosive action on rubber. For instance, it was found that it was absolutely impossible to keep the tires inflated with carbonic acid gas, the gas escaping rapidly through the infinitesimal pores of the rubber. The use of exhaust gases is generally not regarded favorably, because it is known that the vapor contains a certain amount of lubricating oil, and this has a solvent effect on rubber. Atmospheric air is generally regarded as neutral, yet it is known that its oxygen constituent has an oxidizing or ageing effect on rubber, which results in a complete change in its physical properties, rendering it hard and brittle, and very liable to crack. It does not appear to be definitely known whether this effect is due to changes in the rubber or in the sulphur incorporated in it to effect its vulcanization; but there seems to be no doubt that oxygen, the active element of the atmosphere, is responsible for these changes. Following out this line of reasoning, some experiments have been made in France (according to an article by Francis Marre in *Cosmos*) with a view to utilizing the neutral or chemically-inactive element of the atmosphere, nitrogen. According to this writer, the use of nitrogen for this purpose has even reached a commercial stage in France, it being possible to purchase steel bottles containing nitrogen under pressure, which it is only necessary to connect to the tire valves in order to inflate the tires to the desired pressure automatically. When it is considered that atmospheric air is omnipresent and free, the commercial success of nitrogen for this purpose is somewhat doubtful.

SOLID OXYGEN FOR CARBURETER USE.

Oxylithe is oxygen in a latent state—in a solid body that can be treated cold by the simple action of water, in the same way as acetylene gas is produced by the action of water on calcium carbide, but without any of the danger or objectionable smells which accompany the latter. When water comes in contact with oxylithe, oxygen is immediately given off violently; when the water is withdrawn, the generating process stops at once. One pound of oxylithe will, it is said, generate about three cubic feet of chemically pure oxygen; it, therefore, follows that a very large quantity of oxygen gas represents only a very small bulk in the solid. The oxygen only exists in a latent state, and is not generated until actually required. The process therefore dispenses with the use of cylinders of compressed oxygen, and opens up a fresh field in motor carburation research.

TWO AND FOUR-CYCLE TYPES COMPARED

FROM SIBLEY JOURNAL OF ENGINEERING.

FROM 1874 to 1886 the Gas Motoren Fabrik Deutz monopolized construction of four-cycle engines, under protection of German patent No. 532. After a legal fight, lasting nearly four years, and going on at the same time in Germany, Austria, England, Belgium, France and Italy, the scope of the patent was considerably reduced, claim No. 4, covering the four-cycle principle, the especial bone of contention, being vacated. In the meantime, under the force of circumstances, the other manufacturers were compelled to develop the two-cycle engine, and there is no doubt that if the state of affairs as outlined had continued to the end of the patent, the two-cycle engine would have reached its present development much earlier. The very fact, however, that the two-cycle principle in its infancy offered numerous and serious difficulties, made the legal fight protracted and bitter, the pamphlet of Beau de Rochas, of 1862, being a very effective weapon against the validity of claim No. 4. The natural result of the vacation of this claim in 1886 was that the two-cycle machine almost disappeared from the market for nearly ten years, and has found its present development within the last six to eight years.

As stated at the outset, the question of choice between the four-cycle and the two-cycle machine as regards economy, operation and maintenance, is not at all decided, although it must be admitted that the decision commences to lean more and more strongly in favor of the two-cycle. Guldner, especially, to whom we shall be indebted for a great deal of what follows, decides very strongly in favor of the two-cycle machine. Other authorities are not so decided. There is a great deal that may be said for and against each type on both theoretical and practical grounds. Before comparing the two methods as to efficiency, it will be well to outline the conditions attending each.

The two types are thermodynamically equal as far as the combustion of the charge, whether at constant volume, or constant pressure, and their expansion strokes are concerned. They differ only in their method of displacing the old and taking in the new charge, *i. e.*, in their scavenging and loading.

In the four-cycle machine the scavenging is done by the power piston pushing out the burned gases through the exhaust port. This is followed by the suction stroke, during which the new charge is taken in. The compression stroke, combustion, and expansion stroke following complete the cycle. The piston therefore works half the time as a power piston, and the remainder of the time as a pump piston.

In the two-cycle machine the scavenging and loading are done in various ways. In the first place we may distinguish two scavenging agents; the fuel mixture and air alone. Further, the scavenging agent is introduced into the cylinder by pumps in various ways. Among these we may distinguish three types: the enclosed crankcase employed as a pump, the front end of the cylinder employed as a pump, and a pump entirely independent of crankcase or power cylinder. A further modification comes in when any of the above types of pumps are used with or without an air receiver. Several methods of scavenging are also employed. The fuel mixture alone may be used to drive out the exhaust gases, or little air may be sent into the cylinder ahead of the fresh gas, or, finally, the scavenging may be done by an excess of air, followed by the admission of fuel mixture when the scavenging is complete. How these various methods compare among themselves, and with the four-cycle, will be seen later on.

The final judgment upon the success or non-success of an engine should always be based upon the thermal efficiency of the machine at the crankshaft, and upon the mechanical efficiency. Of the power generated during the working strokes of the cycles a part is lost in the fluid friction of the machine, and in the rubbing friction of the various machine parts. The fluid friction in

a four-cycle machine will be understood to mean the pump work as indicated by the bottom loops of the indicator cards. In careful testing these loops should always be taken with a weak spring, in order to determine the pump work with more accuracy. This is especially desirable since little data exists on this point. Should the four-cycle engine be of the positive scavenger type, as the 500-horsepower Premier, reported upon by Humphrey in 1900, this pump work should be added to the fluid friction of the bottom loops. In a two-cycle engine the fluid friction is the pump work done by the fuel and air pumps. The rubbing friction of the machine need not be further defined.

It seems that engineers are not quite unanimous in their methods of computing mechanical efficiency, as the writer had occasion to notice lately in looking over some tests. If from the total indicated horsepower we subtract the fluid friction, in either type of engine, we shall obtain the net indicated horsepower. The mechanical efficiency is, according to some,

$$E = \frac{\text{B. H. P.}}{\text{total I. H. P.}}$$

according to others

$$E = \frac{\text{B. H. P.}}{\text{net I. H. P.}}$$

Guldner consistently employs formula 2, which gives a higher result than formula 1, and takes pains to correct Thurston's figures on a Brayton gas engine computed according to 1. It seems to the writer that the use of formula 2 is justified only when the work of the air pump is to a great extent recovered in the power cylinder, as is the case in a Brayton engine, or in the Diesel. When the air compressed by the pump is, however, used for scavenging only, blowing through the power cylinder when the exhaust port is open, this is not the case, and for such engines, the majority of two-cycle engines, it seems nearer right to use formula 1. Similarly the thermal efficiency at the brake should be:

$$E = \frac{\text{Thermal equivalent of B. H. P.}}{\text{Thermal Units in Fuel supplied.}}$$

A complete comparison of the four-cycle and two-cycle principles should include the following heads:

- I. Thermodynamic actions in the cylinder.
- II. Fluid friction.
- III. Friction of machine.
- IV. Limitations of construction and economic considerations.

TREND OF THE FRENCH MOTOR INDUSTRY.

FROM ENGINEERING.

An interesting fact to be learned is the increasing attention which is being given to automobile construction by the large French metallurgical works, including Messrs. Schneider, the Forges de Douai, and others. Of late years the process of manufacture of chassis has greatly improved, and much attention has been paid to the production of the right quality of steel for the purpose, the first-named works having dealt more especially with the problem and from a scientific standpoint. The French motor car builders manufacture the motors in their own shops, and fit them out complete, together with the whole of the gear; but they are gradually ordering the chassis and the axles more and more from independent French metallurgical works; the plans and technical conditions, however, are drawn up by the car builders.

Alloys of lead, tin, and bismuth show strange properties. Bismuth two parts, and lead and tin one part each, melts at temperature below the boiling point and expands on cooling.

LETTERS INTERESTING AND INSTRUCTIVE

A Corrector Corrected.

Editor THE AUTOMOBILE:

[562.]—I was much interested in letter No. 536, by J. Francis Booream, published in "The Automobile" for January 17, and criticising your answer to Wallace Long's question, No. 497, published in the issue of December 13. Personally I cannot find the fault Mr. Booream seems to find with your answer, and I am wondering if his comments have escaped your detailed analysis. Or is it possible that you now agree with Mr. Booream?

Litchfield, Ill.

HIRAM LEWIS.

Mr. Booream's arguments seem to us quite as erroneous as Mr. Lewis appears to regard them, and the following is the substance of a reply to Mr. Booream, which we have had written for some days. We may be wrong, or perhaps our critic means one thing and we mean another. In any case, we shall be pleased to have him prove his case further. In the answer to Mr. Long, we said that "it is not a fact that the downwardly-moving pistons exactly compensate for the upwardly-moving ones, because the angularity of the connecting rods causes the pistons in the upper half of their stroke to move materially faster than they do in the lower half of their stroke." Mr. Booream says that "in this statement we are wrong." He follows this flat contradiction with a categorical enumeration of six related facts concerning the phenomena involved in the action of a piston, connecting rod, and crank. No exception is to be taken to this enumeration, since he states his facts here with substantial correctness. The point is, they do not apply to the question at issue, except to uphold our side of the argument. To reach briefly the crux of the matter, let Mr. Booream plat the center line, piston, connecting rod, crank circle, and other essential details of a two-cylinder, 5x5-inch vertical engine, with cranks 180° apart, and the connecting rods twice as long as the stroke—ten inches. This done, first regard the situation with the cranks on dead center—one piston clear up and the other clear down. In this position, the volume added beneath the piston that is up, and displaced by the piston that is down, will be ninety-five cubic inches, after making a reasonable allowance for the space occupied by the connecting rod—the area of a five-inch circle being 19.635 square inches, and the ninety-five being secured as 5x19. Now, let the crankshaft be revolved 45°, and the upper piston will drop .75-inch, displacing 14.44 cubic inches, while the lower piston will rise .58 inches, adding 11.02 cubic inches to the crankcase volume. This is a net reduction of 4.42 cubic inches—8.84 cubic inches with a four-cylinder motor—in the volume of the crankcase gases. By continuing the crankshaft rotation another 45° the crankthrows become horizontal, the higher piston having fallen meantime 1.96 inches, displacing 37.24 cubic inches, while the lower piston has risen 1.70 inches, adding a volume of 32.30 cubic inches—a difference here of 4.94 cubic inches. The net result is that each piston has beneath it a volume of 43.32 cubic inches added to the crankcase, a total of 86.64 cubic inches against the 95 cubic inches under one of the pistons before the 90° rotation took place. This means that with a four-cylinder motor 16.62 cubic inches would have to escape from the crankcase during the quarter revolution to maintain the pressure within at what it was. This is not a great deal, but it is enough to prove our point, and a re-reading of our reply to Mr. Long will show that nowhere did we lay any stress upon this particular condition as one of the reasons for breathers. Nevertheless, with very short connecting rods, the closely figured crankcases often used, and the large bores now in vogue, the variations in pressure from the cause referred to might easily become very material. Of course, there is no exception to be taken to Mr. Booream's statement that in a half revolution an equilibrium is reached. A half revolution so obviously reproduces the condition at starting that argument is hardly needed upon a point so obvious.

Concerning Ball Bearings.

Editor THE AUTOMOBILE:

[563.]—Can you tell me why it is that the balls in an annular ball bearing of the Hess-Bright type are not forced against the separating springs by the action of the load during such moments as it is carried practically upon two balls, one on either side of the lowest point of the races? Is it not an objection to ball bearings of this type that some such action may occur under some conditions, with consequent wear, misalignment of shafts, etc.? And is it not a matter of some difficulty to make the springs right to stand the work? An answer on this will oblige me.

Bangor, Me.

CARROLL H. SIMPSON.

The idea that annular ball bearings are subject to some such difficulty as you describe seems to be widely entertained, even by people whose technical knowledge should teach them better. The facts are such as to afford no foundation whatever for the belief, despite its rather astounding prevalence. In the first place, were there such an action, ball bearings of the cup-and-cone type, and of the annular "full type," would be fully as subject to its ill effects as the ball bearings with the separating springs. No ball bearings are made with the races full, there being always a slight space left as insurance against the balls binding against one another. You will realize this when you recall the faint, regular click that accompanies the action of any bicycle ball bearing. This click is due to the balls falling, one after another, over the topmost point of their course, and constitutes in itself all the evidence that could be required to disprove the wedging action suggested as occurring at the bottom of the races. The reason there is no such wedging action is that the load is supported on direct radial lines always extending from the center of rotation. Whether or not the ball positions are such as to make these radii vertical or angular has no bearing upon the case. The point is that, no matter what the ball positions, the stresses upon them are straight crushing stresses, resisted at right angles by whatever portions of the races happen to be behind them. If the two balls, in the case you urge, were on a plane surface, and the load were applied to them through a curved inner race, the balls would be forced apart, but in a bearing the balls are not on a plane surface, being supported by a surface that at all points has the exactly correct curvature to avoid the least tendency to displacement due to the application of the load. Consequently, no resistance is required of the springs in the way of holding against the load. Take all but two balls out of an annular ball bearing some day and you will find that the balls will crush without being separated, no matter how you place them.

The Cost of American and Foreign Steels.

Editor THE AUTOMOBILE:

[564.]—How much more expensive are the imported alloy steels than the domestic carbon steels, and is it a fact that the latter cost as much as the former? I am told, on what I imagine to be pretty good authority, that there is no saving effected by using the poor material, but if this is true why do American automobile manufacturers use anything but the alloy stock? I assume, of course, that there is no doubt of the superiority of the more modern grades.

C. M. CONANT.

Wheeling, W. Va.

It is a fact in many cases that even the difference in cost is not on the side of the carbon steels in this country, and there is probably not much to be said in favor of what any testing machine will conclusively prove the less sturdy material. There are many other factors to be considered, however, besides the mere matter of first cost of stock. The cost of working chrome-nickel and vanadium steels, for instance, may become a decidedly serious matter, and delay in securing deliveries is another—not to be lost sight of by any manufacturer who is in business on a business basis, to make a legitimatæ profit. The highest grade of alloy steel listed by Krupp sells in this country, duty paid, for twenty-

six cents a pound, and the writer knows of a number of cases in which the famous German concern has proved its ability to lay down on the docks in New York City, all charges paid, chrome-nickel steel forgings for less than any American steel-maker would supply them in carbon stock. But the day of this sort of thing is rapidly passing, and America's preeminence in the cheap production of enormous quantities of low-grade structural shapes, rails and the like, seems destined to have added to it a smaller output catering to the growing demand for extraordinarily high qualities. Already several American concerns are specializing on chrome-nickel alloys, and the German boast of two or three years ago that "the whole American steel trust could not duplicate a Mercedes front axle" has ceased to be a fact.

The Practicability of the Original Daimlers.

Editor THE AUTOMOBILE:

[565.]—In answer to the doubts expressed by Robert Miller in the issue of January 10, as to the correctness of my statements about impracticability of certain constructions of two-cycle engines, I would say that I often use the expression "impractical" to signify that an engine equipped in that way will be so much inferior in power efficiency, that in view of the demands for the very best, in this age of thirst for the highest attainments in everything, this dawn of the 19th century, that any construction that cannot be worked out some way, so as to obtain something like ideal action, I call it impractical.

There are often absurd constructions that the best of us may not notice until our attention is called to the reason why it is absurd, but there are few of us whose mechanical instincts are so obtuse that we cannot see it when it is pointed out to us, then we wonder why we did not see it before when it was so very plain, stuck out so conspicuous like. I think that Mr. Miller would be able to see the fallacy of this particular construction, if he was not so influenced by the idea that Daimler had a perfect construction in his engine.

The Daimler engine on its advent into this country, was heralded as the engine that was going to revolutionize the gas engine industry, but the executive of the Daimler people found out that without real merit, no amount of business ability, all of the push, all of the pull that could be brought into use would not build up a reputation; would not make a great and permanent business success of a mechanical mediocrity of achievement.

The trouble with all ordinary two-cycle engines is that they do not get into, or do not retain in their cylinders, a full charge; the fact that they do not develop twice the power that a four-cycle does, when running at the same speed, is positive proof that they do not. With an ordinary crank case compression two-cycle, other than the three-port engine, when the suction stroke that draws the charge into the crank case is completed, ordinarily the vacuum in the crank case will not be filled to completion before the piston begins its return stroke, and compression begins in the crank case, and there will not be as much charge compressed in the crank case as the full piston displacement; when the inlet port opens, and what charge there is compressed in the crank case goes into the cylinder, it will not all go in, the few ounces of pressure left in the crank case when the piston begins its up stroke, represents the amount of charge that should have gone in, but did not. With a mechanically operated inlet to the crank case, with large area and quick action, and with ports of great capacity, these losses at both places are reduced to a minimum, but still you will not get in quite as much charge as you can with the four-cycle construction, with its intake valve made with ample capacity. It is these details of construction that will determine the efficiency or inefficiency of a two-cycle engine, and any obstructions in any of the passages will tend to hinder the free flow of the gases, and will multiply the losses we have just mentioned, and it seems to me to be self-evident that a valve that is held to its seat by its own momentum on its motion being retarded quickly as the piston approaches its center, cannot help but be a very great hindrance to the free passage of the charge into the cylinder, and there will undoubtedly be a great deal more charge left in the crank case than there would have been without this obstruction in the passageway.

There are a number of very difficult problems involved in making a perfect, or somewhere near perfect two-cycle gas engine. The requirements are altogether different from those of a steam engine, a four-cycle, or anything else in modern engineering. All of the functions of a four-cycle are performed by positive means, to get the charge into the cylinder, you use the piston as an air pump to draw it in, when you expel the exhaust, you again use the piston as an air pump to push it out. The two-cycle has no positive way of doing either of these things, but in many respects resembles artillery target practice, it can get there with reasonable accuracy, but will go very wide from the mark unless everything is exactly right, and I believe that it would be easier for one man

to work out all of the things required to be known in order to send a projectile within a foot or so of a target two or three miles away, than to work out all of the problems involved in making a reasonably perfect two-cycle gas engine, but when they are all worked out, the two-cycle will perform all of the functions of a gas engine with a great deal more accuracy than a four-cycle does, and develops the power with much better economy.

Quite a number of years ago I began an exhaustive series of experiments, to determine, if possible, the way to get the charge into a two-cycle engine, and keep it distinct from the exhaust gases, and many other things that I desired to know.

After a few preliminary experiments to determine the exact pressures that an explosive charge would give when it was ignited under different degrees of compression, how long the pressure would stand before it would diminish, etc. I had a 6x8 two-cycle engine made, and planned so that I could easily replace the cylinder with another, whenever I wished to try some different form, as my knowledge developed.

Among my first experiments with this engine, was placing the inlet to the power cylinder as a valve in the piston head. I rather expected that the inertia of the valve would hinder the free passage of the air, and as this was only one of several things that I wished to find out with this series of experiments, I made the valve stem as long as the space would permit, so that I could put a cross bar on it that would strike against adjustable stops in the bottom of the cylinder, when the piston on its down stroke brought the cross bar on the valve stem in contact with the stops, the valve could go no farther, and the piston would go on down to the end of its stroke, leaving the valve open because of its inability to follow. In this way I could find out exactly the length of time that it took to relieve the pressure in the cylinder, so as to avoid igniting the charge in the crank case; I could set the inlet valve so that it would open at such a point that back firing would occur promptly at a speed of 500 r.p.m., or at 1,000 r.p.m., so that it would not occur at the biggest speeds that the engine would ever attain.

With this construction, I found that the engine would run nicely without the stops for lifting the valve, up to a speed of 400 r.p.m. With the stops lifting the valves at the right time, the engine would run 1,500 r.p.m. With the stops, the engine showed 30 per cent. more power under the brake, at all speeds above 200 r.p.m., than it developed when the compression in the crank case had to lift the valve itself.

It is only by making accurate measurements of the power, and everything that conduces to the efficiency or inefficiency of an engine, that we can form anything like an accurate idea of the real merits or demerits of any particular form of construction; if we depend altogether on what it seems to do, we often make blunders and come to conclusions that the facts do not warrant.

Detroit, Mich.

C. P. MALCOLM.

Having collaborated with Mr. Miller in the criticism of Mr. Malcolm's statements, I am, with Mr. Miller's approval, taking it upon myself to refute Mr. Malcolm's reply. To proceed categorically, I am particularly interested in Mr. Malcolm's assumption that the early V-shaped Daimler engines, with valves in the pistons, are "impractical," since it is a most absolute fact that many of these engines are still in use, after periods of service that would do credit to many of the modern designs evolved from them, besides which they are very much more efficient than any modern two-cycle motor. Right now, to-day, one of these engines is in use in the New York Park Department, doing work that it has done consistently and successfully for ten years. And—to dispose of the assertion that this engine "was heralded as the engine to revolutionize the gas engine industry"—is it not definite fact that it was the first practical liquid-fuel engine ever made, and that its direct successors, the Mercedes motors, are at least fairly in line with most modern progress? Surely any contrary view would be a "mechanical instinct as obtuse" as the chronological instinct that characterizes the present time as "this dawn of the nineteenth century." The "trouble with all ordinary two-cycle engines" is, of course, perfectly well understood to be—among other things—the failure to receive full charges. Mr. Malcolm will get no argument on this, nor will any exception be taken to his generalizations concerning the other well-known features of correct two-cycle practice. The points he misses, however, seem rather to be those entering into the problem only when the more serious defects of current practice are eliminated, instead of merely modified. His theories concerning the momentum valve in the pistons, for instance, fall in this category, and are not in any sense proved correct by enumeration of platitudes concerning

the difference between steam engines and gas engines, and between four-cycle engines and two-cycle engines. Nor do I find myself very patient with the idea of "getting the charge in and keeping it distinct from the exhaust gases." Why isn't the solution to be found in getting the exhaust out, really out, first? And certainly it must be admitted that the exhaust cannot be scavenged out by the incoming charge without either wasting charge or scavenging incompletely. So why work seriously along so hopeless a line at all? I can readily understand Mr. Malcolm's success in building a two-cycle engine with a momentum valve that did not work, but before being too sure that the defect was inherent in the use of such a valve, I should want to know how low the terminal pressure above it was dropped before it was expected to open, how much it weighed in proportion to the area it presented to the crank-case charge, and what the result would have been had the possibility of back firing been done away with positively, regardless of speeds or time of valve opening. These considerations Mr. Malcolm has not troubled to touch upon, so until we secure more definite contradiction, I think that Mr. Miller and myself will persevere in our benighted notion that all of the possibilities of liquid-fuel engine improvement are not bound up in mere adaptations of present constructions, and in ill-advised applications of unusual constructions without such more radical alterations as might properly accompany them. VICTOR LOUGHEED.

Information Requisite for 30-day European Tour.

Editor THE AUTOMOBILE:

[566.]—I am contemplating a thirty days' tour abroad in an American-made automobile of 35 horsepower. Can you give me the following information or suggest where I can obtain same?

1. The approximate ocean freight on car weighing approximately 3,000 pounds crated. Would want to ship car on one of best German liners.
2. How much duty on American automobiles going into France and what are necessary steps to get same refunded on returning?
3. Would I have to take out an operator's license in France and Germany, length of time required and expense of obtaining such licenses?
4. Would I experience any difficulty in provincial towns without a mechanician? Can I obtain gasoline that will work O. K. in a Schebler carbureter? JOHN H. PORTER.
Denver, Col.

The cost of shipment of an automobile from New York to a French port (Havre or Cherbourg) varies from \$90 to \$150 according to the steamer and weight and size of car. Crating in New York varies from \$60 to \$100. Inquiries as to transport should be made some time in advance, as automobiles are sometimes refused on the crack liners, being sent on the slower cargo boats. The customs duty on automobiles entering France is \$12 per 220 pounds (100 kilos). When imported for touring or other temporary purposes, the duty so paid will be refunded at the frontier when the vehicle leaves France on presentation of the receipt given at the port of entry. On becoming a member of the Touring Club de France you can, by depositing the amount of customs duty with that body, obtain a license for free international circulation known as a "Tryptique." This can be obtained by correspondence in advance, and on landing the automobilist passes the customs without any formality or the payment of money. The "Tryptique" gives free entry into nearly every European country. Membership in the Touring Club de France is \$1 per year. Members of the A. A. A. are admitted on request; other persons must be proposed by two members of the Club.

An operating license must be taken out in France. The necessary documents are three small unmounted photographs of the applicant, a certificate of domicile, this will be given by your landlord, and a 12 cent sheet of stamped paper, on which must be written a formal demand for a driving examination. These must be sent to the Prefect of the Department in which you are residing. If in Paris, take the papers to the Association Générale Automobile, Place de la Concorde. The driving license issued by this body will cost you \$2, but you will not have to

wait, and you will have no annoying formalities. A French driving license would be accepted for a tour through Germany. Capable repair men are to be found in every town in France; and you would never experience any difficulty by traveling without a mechanician. The gasoline commonly supplied in every store and garage in France and Germany will be quite satisfactory on a Schebler carbureter. You will find useful information on touring in Europe in our issues of March 8, March 29, and May 24, 1906, as well as in the series of articles now running in THE AUTOMOBILE, by Francis Miltoun.

Steam-Engine Cylinders vs. Gasoline-Engine Cylinders.

Editor THE AUTOMOBILE:

[567.]—To settle a dispute, will you please tell me which is better to propel an automobile—one double-acting steam engine cylinder, or four four-cycle gasoline engine cylinders? W. H. TURNER, JR.
Canton, Ohio.

So much depends upon the standpoint from which the comparison of merits is to be made that it is difficult to render a satisfactory decision. Better in what way? If the successful usage of the industry be taken as a criterion, surely the evidence is overwhelmingly in favor of the four gasoline-engine cylinders. Even the very few makes of very successful steam cars are without exception propelled by at least two-cylinder engines, and the writer is not able to recall a single instance of steam-car construction in which the single cylinder has found anything more than experimental application. If you wish a judgment premised upon abstract engineering facts, rather than upon practical results secured, there is much in favor of the steam side of the argument. The four-cylinder gasoline engine has practically a one-throw crank, all of the duplication involved, in the way of a plurality of cylinders, pistons, connecting rods, crankshaft elaboration, etc., being mere details necessitated by the limitations of present types of gasoline engines, to make every up-and-down stroke of the complete engine a power stroke. The single double-acting steam cylinder likewise operates on a single-throw crankshaft, in this case of the simplest possible description, however, and also affords an impulse for every up-and-down stroke. And, more than this, its impulses are better sustained, more flexible, and in other respects materially superior to those secured with the gasoline engine.

CHECK VALVE INLET IN TWO-CYCLE ENGINES.

Editor THE AUTOMOBILE:

[568.]—Referring to the letter of L. R. Wottring in the issue of "The Automobile" of January 17, if it were worth while to start a discussion on the matter, I would like to remind him that almost the only advantage there is to be gained from admitting the charge by check valve through the piston head, is that of locating it at a point of small cubic capacity, so that when only a very small amount of mixture enters the cylinder, as when the engine is throttled down and running very light, the spark plug can be placed where the charge is certain to come in contact with it, so that no matter how small a quantity enters, that quantity will be sure to become ignited. This is an important consideration and his construction will not permit us to avail ourselves even of that, which is the only reasonable excuse for a check valve that could otherwise be dispensed with. C. P. MALCOLM.
Detroit, Mich.

ONE CORRESPONDENT HELPS OUT ANOTHER.

Editor THE AUTOMOBILE:

[569.]—In a recent issue of "The Automobile," that of December 20, 1906, one of your readers asked, in question 508, what could be done to restore the surface and transparency of a celluloid window that had become scratched and dimmed by use. You admitted your inability to solve the problem, and said you would be pleased to have any reader help the inquirer out. I think I can do this. If a worn sheet of transparent celluloid is varnished on the worn side (on both sides if both sides are worn) with a very thin, even coat of any transparent varnish, it will recover practically its original condition and appearance. Probably the best varnish for the purpose is made by dissolving a quantity of transparent celluloid in acetone, making the solution exceedingly thin, and applying more than one coat if necessary. HARRY CHILTON.
Asbury Park, N. J.

FIVE NATIONS TO CONTEST BALLOON RACE.

Fifteen engagements have been regularized for the Gordon Bennett balloon race at St. Louis, next October. The countries represented are France, England, Germany, Spain and the United States, each with three balloons. Italian and Belgian participation is not yet decided upon. The teams will probably be made

up as follows: France, Comte Henry de la Vaulx, Comte George de Castillon and Jacques Balsam; England, Hon. C. S. Rolls, F. H. Butler, A. K. Huntington; Germany, Captain Hildebrandt, Baron Hewald and Captain von Abercorn; Spain, Captain A. Duani, Lieut. Herrera and Senor Salamanca; United States, Lieut. Lahm, J. C. McCoy and one other yet to be decided upon.

Balloons will be inflated in Forest Park, St. Louis, from the Leclède Gas Light Company's plant. Arrangements for the laying of the pipes from the company's tank—the largest in the United States—have already been made,

HOW THE GAS WILL BE CONDUCTED.
Arrangement of pipes from gas works to Forest Park, St. Louis, for the International Aerial Race, October 19.

the plans being as shown in the accompanying sketch. Twenty-four-inch main pipes lead from the tank, with twelve-inch branch pipes running left and right for each balloon, allowing simultaneous inflation. For the first Gordon Bennett balloon race, starting from Paris last year, there were sixteen competitors; thus the American contest is only one short of the number of starters in that immensely popular race.

NOVEL AERONAUTICAL EXPERIMENTS.

LONDON, Jan. 26.—The attention of inventors and mechanical experts of every degree of efficiency having been drawn to aeronautics by the numerous prizes recently offered, experiments are being carried on in every part of Europe with a view to the evolution of that perfect machine which will make the aerial regions as natural to us as terra firma. In the neighborhood of Paris Santos-Dumont varies his attempted flights with experiments of wings and rudders attached to a racing automobile. Captain Ferber, the French expert, rushes along deserted roads with a propeller-driven automobile in his search for the best type of blades and the most perfect equilibrium. M. Bellamy, also of Gallic origin, has taken up his headquarters at Weybridge, England, and is experimenting there with hopes of finally winning the *Daily Mail* \$50,000 prize for successful flight. The apparatus shown in the accompanying illustration has not at first sight any close connection with a flying machine. It is an aero-catamaran, and is used to test the power of various types of screw propellers, and also to find out the positions in which they work to the best advantage. It consists of two attenuated punts, on which are fixed the wheels and frame of an automobile. Above this is a 50-horsepower motor, driving a propeller shaft on which experimental blades are fitted. It is a crude, amateurish-looking structure, but it answers its purpose, driving the slender punts up and down the secluded sheet of water to the satisfaction of its owner.

ANOTHER SUCCESSFUL FRENCH FLIGHT.

PARIS, Feb. 3.—Comte de la Vaulx made another successful trip in his new steerable balloon this afternoon at Sartrouville. Within three minutes of ascending the motor was cranked and the machine described a huge circle at a height of about two hundred meters, traveling at the rate of twenty-two miles an hour. A straight run was next made towards Houilles against the wind, the return run to leeward being performed at a very high rate of speed. After remaining in the air twenty-five minutes, answering its helm perfectly, a successful descent was made. Eighty-eight pounds of ballast were carried. The balloon has now been inflated forty-six days and is still in excellent condition. Much greater speed is expected when the new propellers are fitted.

TRYING TO SOLVE THE AERIAL NAVIGATION PROBLEM BY EXPERIMENTS AT WEYBRIDGE, ENGLAND.

THE Grout Brothers Automobile Company of Orange, Mass., will produce only one model for 1907, with practically no changes on last year's type except in the way of conveniences and appointments. The equipment is specially liberal this year; in addition to the waterproof top a pair of headlights and generator is included. There is an adjustable foot-rest in the tonneau, which will be found a great relief when touring, and a robe rail on the back of the front seat. A roomy box is attached under and at the extreme rear of the car, and with the tool box on the running board, provides ample storage for tools and spare parts. Adjustable stuffing boxes on the counter shaft and main driving shaft and a metal pan under the fly wheel and engine prevent the dropping of oil or grease on the garage floor or street. The body is made of laminated wood with individual front seats and ample room on the rear for three passengers. Standard colors are Merrimac green or royal blue, but other colors are used when requested.

Mechanical Features.—The Grout cars are equipped with a 35-horsepower four-cylinder engine with cylinders cast singly, 4 1-2 by 5 inches bore and stroke. The crankshaft is supplied with 2 1-4-inch bearings between each crank, and are of hammered babbitt. The pistons have four rings and give from 68 to 75 pounds pressure. The valves, which are interchangeable, have a 2-inch bearing and 3-8-inch lift. The engine is carried forward under a metal hood, with a cellular radiator in front of it and a belt-driven fan running on ball bearings. A positive feed lubricator gives the engine the necessary amount of oil, through seven feeds and without check valves. Besides the splash, oil

TOP VIEW OF THE GROUT CHASSIS.

may be supplied to the crankcase through neatly shaped funnels which are fastened to the breathing pipes leading into the hand plate on the side of the crankcase. These funnels are supplied with fine mesh strainers, thus preventing sediment or dirt getting into the crankshaft case.

Ignition is by high-tension jump spark, using single coil for the four cylinders, with a new distributing commutator. All wiring is held in place by supports, preventing all possibility of short-circuiting.

Transmission and Clutch.—A cone-shaped leather-faced clutch is employed. Its dimensions are 2 1-4 face by 16 1-2 inches diameter. Between the clutch and transmission is a universal joint made of heavy cast phosphor bronze. The transmission is of the progressive type, giving three speeds ahead and reverse. Gears have full inch face with teeth beveled on both ends to assure free sliding. Hardened nickel steel stock is employed exclusively for gears. All transmission bearings are of bronze and are supplied with oil holes and wells. The differential is housed in the transmission gearcase.

Drive.—The final drive is through countershaft and side chains. The countershaft is a 1 1-2-inch shaft made of machinery steel running through bronze boxes attached to each side member, these being equipped with extra large grease cups. To each end of the counter shaft is attached a 22-tooth sprocket; each rear wheel carries a 34-tooth sprocket, and Whitney roller chains are employed. Wheels are made of seasoned hickory with steel castings for the hubs. They are 32 by 4 inches in size and mounted on ball bearings.

Steering.—The steering rods and connections are exceptionally large and are adjustable throughout. The distance rod is supplied at each end with the Grout cone bolt, while

to the chassis, and the arrangement is such that the body can be removed without disturbing the mechanism in any way. Waterproof leather is used for the upholstering of the wood body.

TRANSMISSION AND DIFFERENTIAL OF THE GROUT.

the ball and socket joints have spring buffers which take up all road shocks. Steering gear is of worm and sector type. Gas and ignition control is by levers on the top of the steering wheel, the quadrant being stationary.

Brakes.—To each rear wheel is attached two powerful brakes operated by a foot pedal; the emergency brake is of the external contracting type, operated by an outside lever.

Before the emergency brake is applied the clutch is automatically released. The external brake is lined with camel's hair belting.

The Muffler consists of four concentric cylinders with small holes leading from one to the other. The muffler cut-out consists of a plate in the shape of a Maltese cross, which can be rotated to cover or uncover a similarly shaped opening in the end of the muffler.

THE GROUT COMMUTATOR.

Axles.—Both front and back axles are solid, one and one-half inches square, made of three per cent. nickel steel.

Frame.—Armored wood is employed for the frame, the one-fourth-inch steel armor plates forming heavy braces at the corners. The engine frame is channel-steel, well braced, extending backward far enough to support the transmission as well. A fifteen-gallon oil tank of seamless pressed steel

INLET AND EXHAUST SIDE 35-H.P. GROUT MOTOR.

(sufficient capacity to run 175 miles) is supported upon the chassis under the front seats, but not connected with the body.

Body.—Four bolts only are employed to connect the body

AN AMERICAN ON THE AMERICAN INVASION.

PARIS, Jan. 25.—Arthur E. Schwartz, of New York, believes that an American invasion of the European automobile market is feasible and inevitable. Mr. Schwartz is now in Paris, and is supporting his confidence to the extent of looking for a vacant storeroom either in the Avenue de la Grande Armée or the Avenue des Champs Elysées (where they are scarce and high priced), with the idea of installing an agency for American automobiles. The faithful remark regarding "coals to Newcastle" is applicable, but listen to Mr. Schwartz, whose argument sounds like sense:

"I can sell in Paris, at a profit, for about 22,000 francs (\$4,400), an American, four-cylinder 50-horsepower automobile, with open touring body, top and headlights, fully equipped in all details. This would be a first-class machine, the material and workmanship comparing with those of a similar car made on the Continent.

"American automobiles are built strong, having in view America's rough and bad roads, and surely, this quality of strength will never prove to be a disadvantage on Europe's smooth roads. Moreover there are a few bad roads in Europe.

"Now consider the question of speed, as that is always important, and particularly important when we discuss it in relation to France. I am personally interested in a certain make of American automobiles, the Wayne, for instance, which I consider to be among the best, but we will talk about a rival, for which I have plenty of admiration. I refer to the Packard, merely as an example. I have seen a Packard on French roads developing and maintaining greater speed than certain French, German, and other famous flyers—and, mark you, with less noise. I can say as much for the Pierce, which is also becoming well and favorably known in Europe. As for noise, Packards and Pierces make less noise than Panhards, Mercedes, Dietrichs, or even Renaults, which have a special reputation for that much desired quality.

"American motors are less complicated than French motors, and all automobilists must appreciate this feature. An American firm establishing an office in Paris should do things on a liberal scale, and not bury its agency in somebody's garage, where it will be systematically and patriotically interred."

Mr. Schwartz intimates that he is collecting all available information and "pointers" on the subject, to be forwarded to the American Motor Car Manufacturers' Association, which he is representing in a sort of "commercial-scout" capacity.

He maintains that American automobiles, such as Packard, Pierce, Locomobile, Royal Tourist, Peerless, and Wayne, to mention only a few, are rightfully in the same class as Panhard, Mors, Mercedes, Rochet-Schneider, de Dion-Bouton, de Dietrich and Renault.

ANTICIPATING THE AMERICAN INVASION.

PARIS, Jan. 30.—From rumors current, some of the shrewdest selling factors in France are making preparations for the advent of the American-made automobile, and names no less prominent in the trade than those of C. L. Charley and Emile Stern are connected with the rumors. These leading Paris dealers are said to be contemplating the establishment of an agency in Paris to handle American cars. This agency will probably enter into the business already established in the Champs Elysees, under the management of M. Stern, who was formerly the Leon Bollee agent, but who no longer handles that line. His establishment now carries a general line of makes that are well known. M. Charley is the well-known Mercedes representative, but that, it is understood, would not prevent him from becoming interested in the enterprise.

A Car from the Northwest The WOLFE

BUILT by Westerners for the West, is the slogan of the makers of the Wolfe, the H. E. Wilcox Motor Car Company, who have recently opened a factory in Minneapolis, Minn., to turn out cars of the type depicted by the foregoing photograph. A maximum amount of power with a minimum gross weight has been the object of its designer throughout, bearing in mind the fact that it is intended to be used where, to a very great extent, roads are such in name only. For the same reason special attention has been paid to the matter of providing ample road clearance. The car is the result of several years' experience in using and repairing cars on the part of its designer, who has accordingly not attempted to incorporate in it any mechanical novelties or untried inventions, but has taken advantage of his experience and observation during that time to adopt only such features of design as have stood the test of time successfully.

The power plant of the car consists of a four-cylinder, 24-horsepower. Carrico air-cooled engine, the efficiency and staying powers of which have been amply tested in trials carried out under the hardest of service conditions. The cylinder dimensions are 4 by 4 inches, and the motor has a wide speed range. Ignition is by the high tension system, while a Universal carbureter is provided to take care of this essential. A multiple force feed oiler of the mechanical type with independent feeds leading to all the important bearings of the engine is provided for lubrication, the oiler being attached to the engine in such a manner that no amount of shaking or vibration can break off the leads. Lubrication is generally conceded to be by far the most important essential on every automobile engine, and this is particularly the case with the air-cooled engine. The oiler tank itself has a capacity of two quarts, and in order to simplify the matter of oiling and the amount of attention required, advantage has been taken of the false front usually employed on air-cooled cars to provide extra oil-carrying capacity. It has been built out somewhat like the radiator of a water-cooled car, and the surrounding wall utilized to carry a reserve supply of oil. This is supplied through what appears to be a water supply cap for the radiator, and this compartment is connected to the force feed oiler, so that it is only necessary to open a small valve to fill the latter from the reserve supply in this

novel and ingenious tank. It permits of carrying two and a half gallons of oil, which, it is said, are sufficient to last the average autoist for about a month.

A leather-faced cone clutch of the standard type forms the first step in the transmission of the power to the rear wheels, the next taking the form of a three speed and reverse gear-box contained in an aluminum casing, which also houses the differential and countershaft, the final drive being by means of double side chains. In order to prevent damaging the gears an interlocking device is provided, which is so arranged that it is impossible to disengage the pinions before the clutch is entirely out. This is in the form of a pin attached to the pedal; when the clutch is engaged this pin drops into the shifting rod, so that the latter cannot be moved until the clutch is entirely out of engagement. Combining the change speed-gear box and the differential in this manner makes a very compact transmission unit. The double-chain type of drive has been adopted in order to free the rear axle from any encumbrances in the shape of a differential, so that ample road clearance may be provided. Both front and rear axles are perfectly plain, solid bars of square section, 1 1/2 inches in diameter, giving a full 16-inch clearance at all points. The front axle is placed well forward, as is customary with Continental designers, and avoids the necessity of giving it a bend in order to clear the motor. The steering arm is placed forward of the axle; the steering yokes and knuckles are drop forgings of high-grade steel. Both axles have been made of a size largely in excess of that necessary for the car's weight of 1,900 pounds, and, in fact, have a factor of safety of many times that weight. All the wheels run on Timkin roller bearings of generous dimensions.

Suspension is by means of full elliptic springs, both front and rear, experience having demonstrated that this is a type that is particularly suited to the needs of cars designed for use in the western portions of this country. All the springs have been 36 inches in length with an eight inch opening. The wheelbase is 108 inches, and the tread standard, 34 by 3 1/2-inch wheels being employed, the make of tires being left to the option of the buyer. With a standard type side-entrance touring body, and the usual equipment, the car lists at \$1,800.

THE AUTOMOBILE CLUBS OF CHICAGO

LIKE many other organizations which to-day are in a strong and healthy condition, the Chicago Automobile Club, which now numbers its membership up in the hundreds, and which is probably the second in prominence in the country, had a small beginning. Back in 1902, when automobiling was beginning to push itself forward and claim recognition from an incredulous public, the Chicago Automobile Club was formed, at the time, as a voluntary organization. Several enthusiastic devotees met together and formed the organization, formulated a constitution and elected officers as follows: President, Arthur J. Eddy; vice-president, F. C. Donald; secretary, Charles T. Jeffrey; treasurer, Dr. David Cottrell.

The club met at an office in one of the downtown buildings, the Monadnock, and the members worked, heart and soul, to push the movement forward. During this period Mr. Eddy resigned the executive office, and F. C. Donald, whose name is identified with the club from its inception, was elevated to the chair. Stronger and more powerful grew the club in an exceedingly short space of time, and the year after its organization moved into the clubhouse at 243 Michigan avenue, where it remained until May 1, 1906, when the offices were moved into the Fisher building and the new clubhouse was started later in the year at Plymouth court, where the work is now in progress.

July 2, 1903, the organization was incorporated under the laws of the State of Illinois, and the signatures on the articles were: Jerry A. Ellis, Charles E. Bartley, Robert Tarrant, Jr., and Charles W. Gray. The first directors under the incorporation were F. C. Donald, Charles E. Bartley, W. H. Hoops, Dr. F. C. Greene, J. A. Ellis, F. X. Mudd, Robert Tarrant, Jr., S. A. Miles, Charles W. Gray, John Farson, and Dr. F. H. Davis. The objects of the club were: "The promotion and maintenance of a social organization composed of persons owning and interested in the use of self-propelled vehicles for private use; to afford a means of recording the experience of members and other users of automobiles; to promote original investigation in the development of motor carriages; to co-operate with others interested in securing rational legislation, rules and regulations governing the use of automobiles; to promote the interests of owners and users of automobiles against unjust or unreasonable legislation; to maintain the lawful rights of owners or users of automobiles; to promote and encourage the improvement of the highways and generally to maintain a social club devoted to automobilism."

From the time of its incorporation the club has lived up to these objects, and has greatly advanced automobiling interests in Chicago and the State of Illinois. The names of Sidney S. Gorham, John Farson and Ira M. Cobe, especially, are closely connected with the grand growth of the club, and their efforts have always been directed towards the good of the body. Mr. Gorham was appointed to fill the vacant position of secretary in 1904, early in the year, J. W. Dutly having resigned. Since that time he has remained in office continuously, and his efforts, especially on the legal side of automobilism, have been far reaching. John Farson and Ira M. Cobe have held the office of president between them since 1903, Mr. Farson being at the head 1903-4 and 1905-6, and Mr. Cobe 1904-5 and 1906-7. Their rule has been excellent and the organization has greatly prospered under them.

The new clubhouse, into which the members will move this coming spring, will be one of the most complete and handsome of its kind in the world. It is well advanced in construction now, and work is pressing rapidly forward. At the laying of the cornerstone some weeks ago Mayor Dunne assisted, thus attesting the position which the organization maintains in civic affairs. The membership of the club is now limited to 600, which may be increased to a number not exceeding 1,000. Dues and initiation fees have been raised, and the treasury is in a healthy con-

dition. The officers at the present time are: President, Ira M. Cobe; first vice-president, Frank H. Pietsch; second vice-president, Harry J. Powers; secretary, Sidney S. Gorham; treasurer, T. J. Hyman; directors, John Farson, S. K. Martin, Jr., Joseph Gunther, B. H. Marshall, L. E. Myers and Charles E. Gregory.

An Energetic Youngster, the Chicago Motor Club.

The Chicago Motor Club, a new organization devoted to automobiling, was formed early in August, 1906, the incorporators being Charles Root, George G. Greenburg, and William H. Arthur. The club was organized to have proper legislation enacted for automobilists and for inaugurating and conducting competitive events. Under its auspices, in connection with the Chicago Automobile Trade Association, the recent successful economy tour to Cedar Lake, Ind., was conducted, and there has already been outlined a plan for a busy season of interesting events, which will be inaugurated with the advent of spring.

The club has no clubhouse and no social features. Its meetings are held at the New Southern Hotel, on Michigan avenue. It encourages motoring competition, and at present is carrying on a vigorous campaign for the placing of sign boards throughout the State of Illinois and southeast Wisconsin on all main roads leading to popular places; it is endeavoring to have all vehicles carry lights; it is warring on autoists who run away in their cars after causing an accident, or have been the indirect means of causing one, and offers \$50 for the arrest and conviction of anybody so doing; it is taking up the problem of gas search lights for automobiles and other problems which vitally affect the sport.

The organization works hand in hand with the Chicago Automobile Club and Chicago Automobile Trade Association in the reform movements. It is a member of the A. A. A. and the I. S. A. A. There are at present exactly one hundred members in the organization. The membership is not limited. The officers follow: President, William H. Arthur; first vice-president, Joseph F. Gunther; second vice-president, John W. Hayden; secretary and treasurer, George G. Greenburg; directors, Charles P. Root, F. C. Donald, Thomas Hay, Frank C. Riggs and W. L. Githens.

Austin Automobile Club Plans a Great Future.

CHICAGO, Feb. 4.—At the annual meeting of the Austin Automobile Club held last week, Joseph H. Francis, a former alderman, was elected president. The club is in favor of extending and covering all the district in west Chicago from the river to Desplaines. In this way its membership would probably be increased four or five times over what it is now. It was also proposed to change the name of the organization to West Chicago Automobile Club. The following officers were elected: President, J. H. Francis; first vice-president, C. E. Ingalls; second vice-president, J. E. Plew; secretary, E. G. Westwood; treasurer, John Wayman; counsel, A. J. Redmond; surgeon, Dr. B. A. McBurney; directors, the above-named officers, and Charles Burras, A. L. Osterloh and Dr. R. C. Newell.

A committee consisting of President Francis, Secretary Westwood and C. H. Burras was appointed to confer with the West Park Commissioners regarding the erection of a public garage in Garfield Park. President Francis, J. E. Plew, H. M. Lay and John Hemwall were appointed to confer with auto owners in West Chicago in regard to the feasibility of forming the above proposed organization, and were given authority to arrange for a mass meeting of the automobile owners of the district, some 1,200 in number, to be held within two weeks. Preliminary architects' estimates provide for a clubhouse to be located near Garfield Park, costing about \$20,000.

AMONG THE CLUBS IN GENERAL.

Jersey Autoists Will Watch Legislation.

NEWARK, N. J., Feb. 4.—The first gun in the battle of Jersey motorists for a more satisfactory motor vehicle law is to be fired at a meeting of the New Jersey Automobile and Motor Club, which is to be held at the clubhouse of the Newark organization within the next two weeks. At this meeting important questions are to be settled by a vote of all the members of the club, and the decision is to be made as to how the fight in the legislature, if there is to be concerted action by the New Jersey organization, can best be carried on. Last winter, it will be remembered, several hundred of the most influential members of the New Jersey Club went down to Trenton in a body, and had great success in making more equitable some of the provisions of the Frelinghuysen automobile bill as at first proposed by the legislature.

There are two plans of action which will be considered at this meeting. The first is for as many members of all the Jersey clubs as possible to go to Trenton in a body and appear before the legislature committee which will be in charge of any automobile bill which may be introduced. The second provides that a committee of influential members be sent to Trenton with authority to act in the interests of the Jersey automobilists. Whichever of these two plans is adopted, it is certain that all automobile legislation will be closely watched, and any prejudicial to the interests of the automobilist will be vigorously attacked.

Pennsylvania Motor Federation Growing Apace.

PITTSBURG, PA., Feb. 4.—Officers of the Pennsylvania Motor Federation have been doing some solid work during the past few months, and hope soon to have something to show for their efforts. A new motor vehicle law will be introduced which is believed to be a decided improvement on the present law, and encouraging progress has been made in the effort to have introduced a bill providing for a system of State roads and looking to the improvement of the old road connecting Philadelphia and Pittsburg, opening to the tourist its wealth of scenic beauty and historic interest.

Membership is increasing in the Federation, the Wilkesburg Automobile Club and the Automobile Club of Delaware county being the latest acquisitions. Both these clubs organized with a membership of forty. Fifteen clubs are now affiliated with the Federation.

Minneapolitans Will Issue a Club Directory.

MINNEAPOLIS, MINN., Feb. 2.—A booklet containing the names, addresses, license numbers, etc., of the Minneapolis Automobile Club, will be issued shortly. To gather the necessary data for this book, Secretary R. J. Smith has sent out circular letters to all members with an enclosed reply card. Membership cards for the season of 1907 will not be issued until April 1. The new cards will be depositable as bail in case of arrest, as are the present ones.

A bill, which has been drafted by a committee of the club, urging a more careful licensing of autos, consolidating the present State and city speed regulations, and clearly defining the rules of the road, will be introduced in the Minnesota legislature in the near future.

Quaker City Motor Club Election to be Exciting.

PHILADELPHIA, Feb. 4.—With a membership closely hunting the 400 mark, the approaching election of officers of the Quaker City Motor Club, at the Hotel Majestic, is arousing great interest. There is a contest for every office but that of secretary, there being no less than twenty candidates for the nine board memberships. There are three aspirants for the presidency—Charles J. Swam, E. H. Woodman and Nathan T. Folwell, 2d. George H. Smith and Fred T. Chandler will clash for the first vice-

presidency. C. C. Fidler, Jr., J. J. Martin and Nathaniel Hathaway are having a hot battle for second vice-president. For treasurer A. T. Stewart and George T. Thompson are the candidates, while "Dory" Creamer will have a walkover for the secretaryship.

Pittsburgers Will Listen to Practical Talks.

PITTSBURG, PA., Feb. 4.—The Automobile Club of Pittsburg has adopted a novel method of getting new members this spring. Committees of the club are now arranging for a series of lectures on different automobile topics that will be of practical benefit to both dealers and owners of machines. A demonstrator from the different factories will be invited by the club to be present at these lectures and will take the cars apart and otherwise demonstrate the most practical way of getting along with an automobile cheaply and safely. The purchase of a ticket to this series of lectures will entitle the buyer to membership in the club, according to the plans now being shaped up.

Autoists to Organize in Pennsylvania Capital.

HARRISBURG, PA., Feb. 4.—Over a hundred autoists of this city and vicinity met last week and outlined plans for a new automobile club, the constitution and by-laws for which will be formulated without delay. More than 250 automobiles are owned and operated in this city, and with owners of the surrounding towns and newcomers for 1907 it is hoped to have an enrollment of about 500 members. The club is to be very broad in its scope and will take in members who do not own or operate automobiles but who are interested in good roads. At the meeting plans were discussed for the betterment of the roads in the Harrisburg district.

Williamsport, Pa., Organizes an Automobile Club.

WILLIAMSPORT, PA., Feb. 4.—The Lycoming County Automobile Club, with forty charter members, has been organized here, and the following board of officers elected for the first year: President, James B. Krause; vice-president, C. LaRue Munson; treasurer, Charles D. Wolfe; secretary, F. Grant Sweet; captain, J. Walton Bowman. Five members were selected as a board of governors, three as a touring committee, and seven as a legislative committee. Among the members are the most prominent citizens of this city. The erection of a suitable clubhouse is contemplated in the near future.

BRIEF CLUB ITEMS OF INTEREST.

BROOKLYN.—Thirteen new members were added to the rolls of the Long Island Automobile Club at its last monthly meeting, Wednesday, January 30.

CLEVELAND.—The meeting of the Ohio State Automobile Association, originally scheduled to be held in this city during the week of the local automobile show, February 18-23, has been postponed till the early part of March.

BINGHAMTON, N. Y.—Sixty-five covers were laid at the annual banquet of the Binghamton Automobile Club, at the new Armory building, January 29, and the guests included the most prominent automobilists and citizens in the vicinity. An elaborate menu was served.

BUFFALO.—The first annual meeting and banquet of the Motor Boat Club of Buffalo was held at the Markeen Hotel a few nights ago. Flag officers elected for the coming season were: Commodore, U. L. Caudell; vice-commodore, C. A. Criqui; rear-commodore, H. A. Brundige. The four new directors are: Dr. W. Scott Renner, George J. Metzger, J. F. Ellsworth and A. B. Schultz. Plans for the erection of a new clubhouse on Frog Island were laid before the club by Maj. Metzger.

THE AUTOMOBILE CALENDAR.

AMERICAN.

Shows.

- Feb. 11-16.....—Detroit, Mich., Sixth Annual Automobile Show, Light Guard Armory, Tri-State Automobile and Sporting Goods Ass'n. E. E. McMasters, mgr.
- Feb. 18-23.....—Buffalo, Fifth Annual Automobile Show, Convention Hall. D. H. Lewis, manager, Teck Building.
- Feb. 18-23.....—Cleveland Automobile Show, Central Armory, Cleveland Automobile Trade Association. George Collister, manager.
- Feb. 18-25.....—San Francisco, Golden Gate Park Skating Rink. Automobile Show, Dealers' Association and Automobile Club of California.
- Feb. 25-Mar. 2...—Portland, Me., Second Annual Automobile and Power Boat Show, The Auditorium.
- March 2-9.....—Chicago, Second Annual Power Boat Show, Seventh Regiment Armory. W. C. Andrews, manager, 19 E. Huron St.
- March 2-9.....—Minneapolis, Automobile Show, First Regiment Armory, Minneapolis Automobile Dealers' Ass'n.
- March 4-10.....—Kansas City, Mo., First Annual Automobile Show, Convention Hall. Frank L. Woodward, manager, Willis Wood Theater Building.
- March 9-16.....—Boston Automobile and Power Boat Show, Mechanics' Hall and Horticultural Hall, Boston Automobile Dealers' Association. C. I. Campbell, mgr.
- March 13-16.....—Omaha, Auditorium, Second Annual Automobile Show, Omaha Dealers' Association. T. Gillan, manager.
- March 18-23.....—Providence (R. I.) Automobile and Power Boat Show, Infantry Hall. F. M. Prescott, manager.
- April 1-6.....—St. Louis, Mo., Automobile Show, Jal Alai Building, St. Louis Automobile Dealers' Association.
- April 6-13.....—Montreal, Canada, Second International Automobile and Sportsman's Exhibition. R. M. Jaffray, manager, 309 W. Notre Dame Street.
- April 8-13.....—Pittsburg, Pa., First Annual Show of the Pittsburg Automobile Dealers' Association, Duquesne Garden.

Race Meets, Hill Climbs, etc.

- Feb. 22.....—Los Angeles, Cal., Pasadena-Aitadena Hill Climb, Automobile Dealers' Association of Southern Cal.

- Aug. 18-22.....—Ardennes Circuit (Belgium) and Coupe de Liedekerke.

NOW COMES THE AUTO DOG.

"Automobile dogs" constitutes a new classification in the kennel world. Not all kinds of dogs, however pretty they may be, are suitable for the front seat of a stylish limousine. If you have a dog for your auto you must use discretion à la mode in the selection. The auto dog is in the first place an ornament. He is an *article de luxe* and adds considerably to the much desired impression that his owner must be a *costaud*, a swell, for whom expense is a pure pleasure.

The Pomeranian has been elected auto dog. He is called a Pom or a loulou, just as you like, but he always is of that perky spitz species, now so high in public favor—in Paris, at any rate. None other but the Pom will do. A pug or a Scottish terrier or a hairless toy tyke, sitting on the seat beside the chauffeur, would be considered shockingly bad form. The auto Pom ought to be white, to present a striking contrast to the somber shade of the

"MORAT" DISPLAYS GREAT DIGNITY IN HIS VOCATION.

coachwork, and, in order to remain ever white and fluffy, he should not sleep in the garage.

Many dark red or chestnut-colored Poms are used on Parisian automobiles. More white ones would be used if they were more plentiful, but the supply of Pom products from Germany is limited, and the majority are red or black. One of the "most prominent Poms" in Paris is "Morat," who sits on the front seat of Marquis de Dion's automobile, at the side of Zélélé, the chauffeur. Morat is pure white, and Zélélé is Nubian black. Morat is recognized as being the "correct thing" in auto dog styles. The auto dog, besides being the beacon of beauty at the head of the auto, is useful. He guards the vehicle during the chauffeur's absence.

MINOR PERFECTION COMPETITIONS.

Inventors are invited to devote their attention to the minor perfection of the automobile by four competitions announced by that active French body, the Association Générale Automobile. Prizes are offered for the best apparatus to prevent the stealing of automobiles; the best apparatus for showing what is happening behind the car; the best apparatus for hearing sounds coming from the rear, and for an apparatus to measure the quantity of gasoline consumed by the motor.

The Chicago Show Must Be Stamped a Success. With characteristic Western breeziness, and quite in keeping with her well-earned reputation for doing big things, Chicago has successfully achieved what her most able rivals must concede is an effort well worthy of her and a great surprise to the industry which it represents. The Chicago show is, in brief, a revelation. When the curtain was withdrawn early Saturday afternoon, there could be no doubt in the minds of even the "show wise" that here was something well worth coming far to see, and indeed it is. No effort has been spared to make it second to none, which means ahead of anything that has ever been attempted, whether in the West or elsewhere. It is a scene to delight the eye and please the artistic sense, for seldom has such an appropriate setting been prepared for the automobile. And the jewel—the automobile itself—is truly national. It is, in short, the American product from that truly horseless buggyabout native to the middle western soil to the palatial creations of the best known and old established makers in every part of the land. The same is true of the men who devise and manufacture the multitude of things which conduce to the comfort and well being of the autoist, as well as his car. There is absolutely nothing lacking to make the showing as complete as it has ever been the lot of the American enthusiast to find gathered under the same roof, or rather two of them, for Chicago has not one, but two complete and interesting shows.

The Vital Question of Tire Values. Perfection in construction and operative qualities of automobiles has reached such a high standard that the arrangement of a well-defined touring schedule may be made by any automobilist with a

reasonable surety of the same being carried out—with the exception of the tires. This is a subject closely allied to the autoist's pocketbook. What tires shall be fitted to the car? To the experienced owner this question is non-debatable. With him price does figure, quality is essential, and he knows from costly experiment that a tire of unknown quality is expensive at any price. With the automobiling novice exterior appearances in tires are much the same, and his safeguard is to purchase his wares from reliable makers, or their accredited representatives.

This year crude rubber is dearer than it has ever been before, with every prospect of advancement in price as the season progresses. Some tires will be cheaper, but will the automobilist benefit? Will the manufacturer reduce the price and improve the quality? Bicycle tires can be purchased for a couple of dollars a pair, but the standard makes, those made by manufacturers to wear, cost more than they did several years ago, when the sale was greater, and are more in demand than the cheaper grades.

Notwithstanding the increased price of rubber, automobile tires are cheaper to-day than they have ever been, not in actual price, but in wearing qualities. Manufacturers of tires of standard makes are spending fortunes to improve their products, and the coming year will demonstrate tires that last longer, wear better, and give less trouble than ever before, and the automobilist who insists on tires of known value on his car will appreciate this at the end of the season.

Talking Points Should Become Unnecessary. In the last analysis, what is the one thing most sought after by the purchaser of a car? Is it the glamor of fine finish and polished parts that takes his fancy and decides his choice, or is it the certainty of reliability in action, and, what is equally important, durability, that led him to prefer one make rather than another? The question may be answered equally well one way as the other, and such will continue to be the case as long as human nature remains what it is. Just as a woman makes her choice because the upholstery of the car is such a "lovely" shade of fawn, so many a more practical purchaser finds his admiration aroused by the exterior finish of the motor or the presence of some particular feature of construction which he favors, and ignores all other essentials in making his selection. Entirely too many makers continually strive to keep their productions in the limelight by virtue of the "talking" points with which they cover them. They make the mistake of pandering to the perverted taste of the buyer who considers the car that is covered with new gimcracks every year as being representative of the most advanced type.

"What's new on your car this year?" is a query that is heard all too often at the shows, and unfortunately a failure to respond to it by revealing some marvelous and alleged revolutionary departure that is claimed to place it years ahead of all others, gives this type of buyer the impression that the builders of that particular car have fallen into a rut from which they are unable to emerge. The conservatism which benefits from experience and clings to what time and service have shown to be fundamentally and mechanically correct, is erroneously regarded as lack of progressiveness. Education must be gradual to be sure, and that it has not been more rapid or widespread in this particular respect is largely due to the attitude of the manufacturers themselves. The almost total abandonment of the preceding year's work in favor of something radically different that was uncovered for the first time at the annual show was the natural concomitant of the unsettled state of early days. There are too many makers, however, who have not yet come to a realization of the fact that those days are a thing of the past.

Meretricious "talking" points are now more apt to disparage a car than otherwise—it is a natural conclusion that its sale depends upon them, and they have absolutely no other *raison d'etre*. They still appeal to a certain class of buyers, and probably always will, but education is constantly thinning its ranks. It may be added that one of the best known cars made still embodies the principal features of construction that distinguished it six years ago—it runs—and that is what sells it. No mere talking or selling points are required.

A. A. A. RACING BOARD FOR 1907.

Following out the policy of centralization inaugurated by President Hotchkiss, the 1907 Racing Board of the American Automobile Association is much smaller than the board of last year. Chairman Jefferson de Mont Thompson has received a well-deserved recognition of efficient service in his re-appointment to that responsible position for another term, his colleagues on the board being William K. Vanderbilt, Jr., E. R. Thomas, Dave Hennen Morris, Frank G. Webb, A. G. Batchelder, S. M. Butler, all of New York; A. R. Pardington, Brooklyn; R. L. Lippitt, Providence, R. I.; George L. Weiss, Cleveland, Ohio. Frederick H. Elliott, secretary of the A. A. A., will act in a like capacity for the Racing Board.

A. L. Riker, Bridgeport, Conn.; E. R. Thomas, Buffalo, N. Y.; and Henry Ford, Detroit, Mich., will continue their duties as technical advisors to the board, and to their number has been added J. J. Mann, Paris, France. Mr. Mann resides in Paris and is chief engineer of the Hotchkiss Gun Factory and designer of the Hotchkiss car. He is a member of the Automobile Clubs of France, Germany and Great Britain, and of the Touring Club of France.

There is scarcely any doubt but that the Vanderbilt Cup race will again be run in this country this year. The Automobile Club of Italy, which has first claim on the Cup contest by reason of the French Club's refusal to officially participate in the race, is in favor of having the race run here, and this desire is also shared by the Italian manufacturers who have entered cars in the past races. There is no doubt that the German Club also wishes to have the race decided on American soil. While in Europe, Mr. Vanderbilt will make a careful study of the regulations governing the 1907 Grand Prix of the Automobile Club of France, and also the rules for the Targa Florio in Italy and the race for the German Emperor's Cup. He will present the result of his investigations at the first meeting of the 1907 Racing Board, which will be held soon after his return to this city.

GRAND PRIX LIST STILL GROWING.

PARIS, January 27.—Engagements for the Grand Prix of the Automobile Club de France now number twenty-two, the firms represented being Bayard-Clement, Darracq, Motobloc, Corre, Panhard, Renault, Lorraine-Dietrich, and Germain, all French, except the last named. Le Blon, who last year drove a Thomas car in the Vanderbilt Cup contest, has signed an engagement with the Panhard firm for the great French race next July. Heath will again pilot a Panhard. The third driver is said to be a sportsman who has not previously figured in big automobile races. The three Belgian cars, Germain, will be piloted by Perpere, Roch-Brault fils and Degrais, all three men who have yet to make their reputation in France. In eight days from this date the engagement list at ordinary fees will be closed. In the meantime it is expected that the Brasier firm will send along a cheque for three thousand dollars in order to have the privilege of running three Treffe à Quatre racers for the Grand Prix, and that Civelli de Bosch will do likewise. Foreign participation is not likely to be very numerous, but an appealing look is still being directed towards Mercedes, Fiat, Itala and Rolls-Royce. Two firms, Falconnet-Perrodeaud and Hutchinson, are now engaged in the tire competition to be run as an auxiliary of the speed contest. Neither of these two firms has previously been represented in an important French road race, and their appearance this year is a sure indication of fresh competition for the old guard—Michelin, Continental and Dunlop. There is every probability of the Seine-Inférieure being chosen as the scene of the Grand Prix, Dieppe and district having offered a subvention of \$20,000 to the A. C. F.

In its passing from a weekly publication into a monthly, *The Motor Way* says the industry has "no use for a weekly." Why not spell it with an "a" and bring out an annual—which will be often enough.

DATES FIXED FOR EUROPEAN TOUR.

On May 13 American automobile manufacturers will commence their pacific invasion of Europe. The committee in charge of the arrangements for the American Gold Cup tour has fixed upon this day as the date of embarkation for all machines entered for the 4,000 miles run over foreign soil. Entries for the tour will close on the first day of the same month, the entrants being confined exclusively to American made automobiles. Every car entered will be carefully examined by the technical committee in charge of the tour before it is permitted aboard ship, and the right to refuse any mechanically unfit vehicle is reserved. A number of picked mechanics from different factories will accompany the cars. After speeding over the highways of France, throwing up the dust of Italy, struggling through Germany, and exciting the curiosity of the automobile-loving Parisian, the machines will be shipped over to England. A run northwest to Liverpool, with naturally a pause in grimy London *en route*, will bring the travelers to the end of their journey. Before re-embarking a series of hill and speed tests will be held in the neighborhood of the great seaport.

Primarily a traveling exhibition of the American automobile industry—and as such it is opportune, for Europe is intensely interested in America's auto developments—the tour will be an excellent opportunity for seeing Europe to the best advantage. Paris will be reached at the height of its social season, the Grand Prix and the German Emperor's race will be witnessed, London will be visited during that brief interval when the city fog is entirely absent, and the run through France and other Continental countries is timed to have best weather conditions.

DE DION AGAIN DEMANDS TOURING TEST.

PARIS, Jan. 28.—The Marquis de Dion, vice-president of the Automobile Club of France, and a strong upholder of touring as against racing events has, undaunted by the failure of his huge touring scheme of last year, brought forth another plan for the development of the touring automobile. His programme is to send the touring machines off about the end of June on a lengthy tour in the southwest of France, to finish up with a run at high speed over a circuit in the neighborhood of Trouville in early September. Machines which have failed to maintain an average speed of 25 to 28 miles an hour in the touring test will not be allowed to start in the race, the classification of which will alone decide the winner. Freaks will of course be eliminated by the long distance to be run under purely touring conditions, and by the fact that the competing machines must weigh at least 2,750 pounds. The plan of a long preliminary run under touring conditions ending by a speed test for the survivors with perfect scores is one already frequently adopted for minor French contests with admirable results. It is the first time, however, that it has been proposed for an event of really great importance.

PARIS, Jan. 30.—The long-distance tour and race proposed by the Marquis de Dion has been received with enthusiasm by the French automobile industry. The competition will be for four-seated touring machines weighing not less than 2,750 pounds, with a maximum fuel consumption of 3.5 gallons per 62.1 miles.* A preliminary tour of about 2,000 miles will be made under purely touring conditions, and at a fixed minimum speed. Only cars having fulfilled the conditions of the long-distance tour will be allowed to participate in the final, which will consist of a 250-mile speed test over a circuit near the fashionable seaside resort of Trouville. An excellent course has been found, with long, straight, undulating stretches and ample width throughout. The final will be run in the month of August, at a time when Trouville and district is crowded with visitors. The trophy is to consist of a gold cup given by the Automobile Club of France, and a number of gold medals given by French newspapers to be incorporated in the cup. It will be known as "La Coupe de la Presse"—The Press Cup.

*The British Tourist Trophy race requires 87½ miles to be covered on 3½ gallons of gasoline.

FEAR FEATHER-WEIGHT RACERS.

PARIS, January 28.—First announced to the public but a few days ago, no time has been lost in drawing up the regulations for Grand Prix No. 2, or as it is now officially designated, the Sporting Commission Cup. In all essentials the regulations are akin to those governing the French Club's annual road race, excepting that the fuel allowance is reduced by one half. Thus, instead of 30 litres per 100 kilometers the Sporting Commission racers will be allowed but fifteen litres, or 3.3 gallons per 62.1 miles. The gasoline tank must be sufficiently large to contain the full amount of fuel allowed for the race. As the total distance is about 500 kilometers (310 miles) sixteen and a half gallons of gasoline will be carried. There will be no controls or neutralizations of any kind, and, as in the Grand Prix, all work on the cars must be done exclusively by the driver and his mechanic. A uniform type of gasoline tank must be adopted, a model of which will be issued to the competitors in due course. Although this point is not yet definitely settled, it is expected that the Sporting Commission Cup will be run the day before the Grand Prix. No weight limit is imposed. French critics regard this as the weak point of the race and attribute the lack of entries—three Gillet-Forest are the only machines officially engaged—to this clause. They ask that a minimum weight of 2,200 pounds be imposed. Rumor has it that one of the most important French factories will turn out a 50-horsepower machine weighing only 1,100 pounds (22 pounds per horsepower), consuming 4 3-4 gallons per 100 miles, and capable of 75 miles an hour. With such a low weight there would be very little tire trouble and the average speed for the entire distance would probably be higher than that furnished by the more powerful racers. The object of the Sporting Commission Cup was to allow the smaller firms, unable to build three special high power racers, to compete in an important contest, and at the same time to develop a type of machine having some relation to a standard touring car. Without a weight limit one of these objects would certainly be defeated. Hence a cooling down of the first enthusiasm for the Sporting Commission Cup.

ENTRIES FOR THE TARGA FLORIA.

Engagements up to date for the Targa Floria, the Italian national automobile race to be run on April 21, over a 400 miles course in Sicily, are as follows:

Fiat (4) Nazzaro, Weillschott, Lancia, —.
Itala (4) Cagno, Fabry, Graziani, —.
Dietrich (3) Duray, Rougier, Gabriel.
Gobron (3) Rigoly, Gobron, —.
Benz (3).
Lucia (2).

Darracq (2) Wagner, Hanriot.

The Targa Florio is a road speed contest for four-cylinder machines with a bore not less than 120 mm. or more than 130 mm., and for six-cylinder cars with a cylinder bore between 76 and 89 mm. A weight limit of 2,200 pounds is fixed for the minimum bore, with an allowance of 44 pounds for every millimeter above the minimum. In addition to the Cup or Targa to go to the winner, a reproduction in silver will be offered to every driver finishing a race, and \$7,000 in cash will be distributed among the first five arrivals.

LANCIA'S NEW AUTO FACTORY DESTROYED.

Lancia's proverbial ill luck has followed him even in his new business connections. Recently the daring Italian driver formed a company for the construction of a popular type of automobile and erected a large factory at Turin, Italy. A cable report just received from Europe announces that the new factory has been completely destroyed by fire. The damages amount to \$20,000. Three firemen were injured and many workmen have been thrown out of employment. Although Lancia has severed business connections with the Fiat firm, he will drive their cars in this year's prominent racing events, including the Grand Prix.

NEW BOOKS FOR AUTOMOBILISTS.

Hungary as Touring Ground for Americans.

Americans who contemplate a tour through Europe will certainly find something to interest them in the booklet published by the Guide Strangers' Inquiry Office, Vigado-Ter, Budapest, IV., entitled, "A Week in Budapest and Hungary." Of the thousands who annually visit the old continent, very few extend their excursions as far as Hungary. It is a pity, for Budapest has natural and architectural charms of a high order, and the banks of the Danube, the High Tatra, the famous Dobsina "Cave of Ice," and such Upper Hungarian watering places as Fenyohaza, Postyen, etc., have charms equal to any of the better known portions of Europe. Numerous illustrations and descriptive text give some idea of the charm of touring through this romantic country. American automobilists are assured of a hearty reception and every assistance in the matter of information from their colleagues of the Hungarian Automobile Club.

Alcohol and the Methods of Its Treatment.

"Distillation of Alcohol and Denaturing" (\$1 net) is the title of a 200-page book on a timely subject, by F. B. Wright, which has just been issued by Spon & Chamberlain. It treats of the various methods of producing alcohol as well as the numerous materials available for the purpose, including a chapter on alcoholometry. The subject of denaturing is gone into very thoroughly in connection with the Free Alcohol Act and the Internal Revenue Regulations.

A Dissection of the Automobile in Book Form.

What might aptly be termed "the automobile dissected," forms the subject of a convenient handbook just issued by John Wiley & Sons under the title of "The Complete Automobile Instructor." It is by Benjamin R. Tillson, director of the H. J. Willard Co. automobile school, who has put its contents in the form of a series of questions and answers. The motor and its various accessories are treated independently, making the volume convenient for reference. There are over 600 questions, with 50 illustrations, covering 213 pages; cloth, \$1.50; morocco, \$2.

STRINGENT LAW PROPOSED FOR INDIANA.

INDIANAPOLIS, IND., Feb. 4.—It was not expected that the present Indiana Legislature would attempt to change the automobile law passed two years ago. Most unexpectedly, however, a bill that would practically replace the present law has been introduced by Representative Frump, of Clay County. Mr. Frump bases his bill wholly on the complaints from his own county that drivers have not respected the speed law. There is no evidence, however, that any effort has been made to enforce the speed provisions of the present law. In the two years the law has been in existence there have been less than fifteen arrests in all parts of the State for various violations.

The bill now under consideration provides that automobiles shall slow down to three miles an hour in passing other vehicles, the present law providing a speed of eight miles an hour under such conditions. Automobiles must also slow down at crossings and curves, and the size of license numbers is increased from four to eight inches in height. Stringent penalties for violations are attached. The fine for the first offense is increased to a possible \$300, second offense to a possible \$800, and for the third offense a jail sentence of thirty days may be added.

Automobile men will be given an opportunity to appear before the Road Committee of the House of Representatives and discuss the bill. There is such a sentiment against fast driving in rural districts, however, that even if the bill is not passed, it will be reported favorably to the House by the committee and fought out on the floor.

WITH THE MOTOR BOATS AT PALM BEACH.

PALM BEACH, FLA., Feb. 1.—Cleaving the placid waters of Lake Worth like a thing of life, lithe-bodied *Dixie*, her sides smooth as glass, and her whole frame aquiver with the vibrations of her 133-horsepower engine, to-day placed the motor boat record for the nautical mile at 2:21.32. The trials were a fitting climax for a string of victories achieved by the *Dixie* in the four days of racing, and her owner, Commodore E. J. Schroeder, of the Motor Boat Club of America, is justly proud of her. On the first day an overheated bearing caused her to withdraw prematurely from the fray. The defect was promptly remedied, and when the meeting came to a close *Dixie* was on everybody's lips and her owner was the happiest man at Palm Beach. Three first prizes on the second day, two firsts on the third day, two more on the fourth day, and a record as a final *coup*, constituted a brilliant performance. But to take the events in chronological order.

Brilliant weather, an elegant crowd—and an enthusiastic one withal—watched the two morning and the three afternoon races of the opening day. *Katherine*, *Gray Wolf*, *Bruiser* and *Dixie* got away for the first race, distance nine nautical miles, for boats over 80 rating. Up to three-quarter distance *Dixie* appeared a winner; then her bearing warmed up, and she retired in order not to destroy her chances for the entire meet. J. Middleby, Jr.'s, *Katherine* carried off first prize, with *Gray Wolf* and *Bruiser* in her rear. In Class A, for smaller boats under 80 rating, there were ten starters, among them being several new comers. Smith & Mabley's *Simplex VIII.*, starting sixth, soon overhauled the others, and H. A. Broessel piloted her through to first place after a keen struggle with *Hot Stuff VI.* *Simplex VIII.* obtained another victory in the afternoon, when she beat *Possum*, *Hot Stuff* and *Baby Bullet*. All the small boats except *Hot Stuff VI.* started in a mixed race with the three big craft over a ten-mile course, in which *Simplex VIII.* again proved a winner, with *Katherine* and *Gray Wolf* a good second and third.

A collision between the *Bruiser* and the *Katherine* on the sec-

ond day gave a subject of conversation to the sensation mongers, but it was forgotten in the fine performance of the *Dixie* in covering ten miles in 22:08, thus establishing a Lake Worth record. In a five-mile race in the same class she won in 11:08. It was, however, in the fifteen-mile race, Class Z, that the *Dixie* showed her highest rate of speed, her time being 32:51, equal to almost 28 1-2 miles an hour, and not far from the world's record.

The *Dixie* had an easy task in the third day's events, for in the five-mile race *Gray Wolf* was her only competitor. *Dixie* gave her five minutes start, and won in 11:30. In another race at the same distance *Dixie* had a walkover, finishing in 11:20. A five-mile race for all boats, the best of the day, was won by W. V. Covar's *Planet*, the *Dixie* being second with a slight lead over *Simplex VIII.* The *Planet* captured first place in a five-mile race for Class X, with *Simplex VIII.* second, and *Errand Boy* third, out of seven starters. Lieutenant H. E. Willoughby's *Possum* won in a field of five boats in Class X, with the *Errand Boy* second, and *Baby Bullet* third.

On the final day excitement ran high, and when the trim, speedy *Dixie* captured the Sir Thomas Dewar trophy with a record for the nautical mile, her owner and her crew came in for a hearty burst of cheering. In a special five-mile race for the speedier craft, the *Dixie* again came out winner. The *Swallow* had a big start, and for some time it looked as if the *Dixie* would not be able to catch up to her. Inch by inch, however, she crept up to her opponent. During the last few seconds her bow showed in front of the *Swallow's*, and final victory was secured by barely a length. A twenty-mile endurance test, with all boats handicapped according to their performances, *Dixie* starting scratch, brought the regatta to a close. Her 133-horsepower, eight-cylinder S. & M. Simplex engine throbbing with perfect regularity, the *Dixie* covered the distance in splendid style, and added the Wanamaker Cup to her long string of trophies.

The *Dixie's* mean average of 2:21.32 was based on six runs over the measured mile, three being with the tide and three

SWIFT-MOVING "DIXIE" THAT PLACED RECORD FOR THE NAUTICAL MILE AT 2:21.32, MEAN CORRECTED TIME.

MAKING READY AT THE LANDING FOR THE RACES.

against. This record only very slightly surpasses that of the *Standard*, which on the Hudson last fall placed the nautical mile record with and against tide at 2.22. The difference in the conditions of the two tests will be realized when it is stated that between the *Standard's* runs with the tide and those against there is a variance of 24 seconds.

Summaries of the Regatta—First Day.

CLASS A. 80 RATINGS AND BELOW, 41-2 NAUTICAL MILES.

1. Simplex VIII., 30-h.p., Owners, Smith & Mabley
2. Hot Stuff.
3. Possum, 28-h.p...Owner, H. L. Willoughby
Also ran: Planet, Baby Bullet, Klots, Mera, Blanche, Errand Boy.

CLASS B. RATING 80 AND ABOVE, 9 NAUTICAL MILES.

1. Katherine, 40-h.p.....Owner, J. Middleby
2. Gray Wolf, 30-h.p., Owner, H. L. Willoughby, Jr.
3. Bruiser, 50-h.p.....Owner, J. K. Clarke
Dixie withdrew, with heated bearing.

CLASS A. RATING 80 AND BELOW, 41-2 NAUTICAL MILES.

1. Simplex VIII., 30-h.p., Owners, Smith & Mabley
2. Possum, 28-h.p...Owner, H. L. Willoughby
3. Hot Stuff.
Also ran: Baby Bullet, Blanche, Errand Boy, Mera, Planet.

CLASS B. 80 RATINGS AND ABOVE, 41-2 NAUTICAL MILES.

1. Gray Wolf, 30-h.p., Owner, H. L. Willoughby, Jr.
2. Katherine, 40-h.p.....Owner, J. Middleby
3. Possum, 28-h.p...Owner, H. L. Willoughby

CLASS C. ALL RATINGS, 9 NAUTICAL MILES.

1. Simplex VIII., 30-h.p.....Owners, Smith & Mabley
2. Katherine, 40-h.p.....Owner, J. Middleby
3. Gray Wolf, 30-h.p.....Owner, H. L. Willoughby, Jr.

"KATHERINE" LEAVING HER BERTH FOR STARTING LINE.

Second Day.

CLASS X, LESS THAN 30 FEET, 41-2 NAUTICAL MILES.

1. Mera, 20-h.p.....Owner, W. I. Huffstetler
2. Planet, 5-h.p.....Owner, W. B. Covar
Also ran: Blanche, Baby Bullet, Hot Stuff and Possum.

CLASS Y, MORE THAN 30 FEET, 9 NAUTICAL MILES.

1. Dixie, 133-h.p.....Owner, E. J. Schroeder
2. Katherine, 40-h.p.....Owner, J. Middleby
3. Gray Wolf, 30-h.p.....H. L. Willoughby, Jr.
Also ran: Kloto, Simplex VIII., and Bruiser.

CLASS X, LESS THAN 30 FEET, 9 NAUTICAL MILES.

1. Baby Bullet, 12-h.p.....Owner, G. J. Paddison
2. Mera, 20-h.p.....Owner, W. I. Huffstetler
Also ran: Blanche, Planet Errand Boy, Possum.

CLASS Y, EXCEEDING 30 FEET, 41-2 NAUTICAL MILES.

1. Dixie, 133-h.p.....Owner, E. J. Schroeder
2. Gray Wolf, 30-h.p.....Owner, H. L. Willoughby

Also ran: Baby Bullet, Mera and Swallow; Dixie withdrew.

Fourth Day.

CONSOLATION RACE, 41-2 NAUTICAL MILES.

- Gray Wolf, 30-h.p.....Owner, H. L. Willoughby, Jr.
Errand Boy, 12-h.p., owner, G. S. Andrews, did not finish.

SPECIAL RACE, 41-2 NAUTICAL MILES.

1. Dixie, 133-h.p.....Owner, E. J. Schroeder
2. Swallow, 30-h.p.....Owner, C. J. Swain
3. Gray Wolf, 30-h.p.....Owner, Hugh L. Willoughby, Jr.
4. Katherine, 40-h.p.....Owner, J. Middleby

ENDURANCE RACE, 18 NAUTICAL MILES.

1. Dixie, 133-h.p.....Owner, E. J. Schroeder
2. Gray Wolf, 30-h.p.....Owner, H. L. Willoughby, Jr.
Also ran: Blanche, Planet, Mera, Baby Bullet, Swallow.

NAUTICAL MILE RECORD TRIALS.

Dixie made six trials, three with the tide, three against the tide; best time with tide, 2:19; best time against tide, 2:21 1-5. Mean corrected times, all trials, 2:21:32.

SHOWN FOR THE FIRST TIME IN CHICAGO.*(Continued from page 273)*

Monarch Motor Car Company, 404 Monadnock Block, Chicago.—The company reorganized under this name and which has established a modern plant for the manufacture of cars at Franklin Park, Ill., is showing an improved form of light-weight and speed general service runabout, which resembles its predecessor in name only. The two-cylinder horizontal opposed engine, with the Monarch air-cooling device, rated at 14-horsepower, is placed transversely at about the center of the chassis on a reinforcing frame connecting the side spring members, which in turn connect the front and rear axles. This strengthening frame also supports the planetary gear as well as the bearings for the propeller shaft, thus making a unit power plant. Ignition is by jump spark through timer and double coil, using dry cells, control both of spark and throttle being placed on stationary sector over steering wheel. Lubrication is by compression grease cups throughout with exception of cylinder oil cups. The wheel-base is 78 inches, tread standard, and 28 by 3 inch wheels are employed on which the buyer has an option of 3-inch Good-year Universal Detachable tires or 2 1-2-inch cushion tires. The weight of the complete car is 750 pounds. With a piano box body, leather upholstered and full tool and lamp equipment the car lists at \$600 or \$650 with top; the Stanhope or type B with 45-inch seat and best leather upholstery and top lists at \$800; a Victoria, type C, at \$850, and Model E, with complete equipment, at \$900. In addition to these a light delivery wagon with a 1,000-pound capacity, is listed at \$750. It is made with any style top or body desired.

Western Malleable Steel Company, Detroit, Mich.—Castings and drop-forgings for automobile and motor boat use are produced by this firm on a large scale. Their plant at Detroit, which has now been in operation a little over a year, has been designed with a view to providing every modern facility for turning out this class of work on a large scale, and the favorable attention its products have received has more than fulfilled the anticipation of its sponsors. The malleable steel castings specialized by them are made from iron imported especially for the purpose, which when refined for the end in view, produces castings true to pattern, solid, tough and homogeneous, easy to machine and difficult to break by bending or twisting. By this process they have succeeded in turning out gear blanks from 2 to 24 inches in diameter, absolutely solid and free from blow holes. They are also equipped to turn out high grade gray iron castings, such as are required for cylinder work, pistons, rings and tool needs, using a dry-sand molding process that meets all requirements. The tool department is fitted out with every modern facility for die stamping, and drop-forge room has 24 presses ranging from 1,000 to 3,500 pounds, permitting of the production of one piece front axles, one piece six throw crankshafts in any material, including nickel chrome steel. They are also equipped with every facility for pattern-making and can undertake the production of special parts from beginning to end.

National Sewing Machine Company, Belvidere, Ill.—This firm controls the well-known Crandall system of lubrication for high speed machinery which is especially adapted to the needs of the auto and motor boat. Its utter simplicity, as well as its "foolproofness," are the chief recommendations of the Crandall lubricator. There is but one large pump, instead of multiplicity of small and vexatious parts; it is set to furnish a much greater quantity of oil than is required for the feeds, and needs no adjustment, the surplus passing through a pressure valve which is absolutely positive in its working, and which is permanently set at the factory and

placed in a part of the machine where the man afflicted with "tinkeritis" cannot reach it. One of the claims made by the makers is that the sight feeds of the Crandall will not "back down" or "cloud the glasses," as it is commonly called, while the lubricator is idle. That is, the glycerine or water in the sight feeds is positively retained. Its working is instantaneous, for as soon as a drop of oil is forced into the liquid sight feed, which is of highly ornamental design, a corresponding drop passes through the check valve and to the bearing. All the feeds are constantly maintained full of oil by the automatic check valves.

Excelsior Supply Company, Chicago.—Among the numerous specialties shown by this concern and for many of which it is the exclusive, either in Chicago or the Middle West, are the "B" line oil guns, "the handy gun for unhandy places," some of the best types of which are the "Back Bay," the "Broadway," the "Boulevard" and the Boston combination oil and grease guns, as well as the "Bourse Primer," which is a handy thing to have along for starting cold weather. Then there are the "Dure" Ignition accumulators, made by the Chicago Battery Company, which company also makes auto and motor boat annunciators, ignition and lighting wire, lighting dynamos, searchlights, front, dash, dome and tail lights, beside a number of others for special purposes. The "Stapley" compound tire pump, with pressure indicating gage, is another that has come in for considerable favorable comment. In the field of speed and distance recording instruments, they show the Winchester "speedodometer," combining a trip and season mileage recorder and a speed indicator, working on the centrifugal principle. These instruments are thoroughly tested for every point of the card of their calibration, so that the makers guarantee them to be absolutely accurate at every mile or fraction from one to sixty miles per hour. Permanent lubrication is provided for in their making, so that no further oiling is necessary.

Auto Accessories Manufacturing Company, Chicago.—As its name indicates, this concern manufactures a number of specialties in the shape of auto accessories, on many of which it is the patentee, such for instance, as its patent adjustable lamp bracket, designed to fit any model car and to take any type of lamp with equal facility. Another is their adjustable extra tonneau seat, which can be taken apart in a few minutes and stowed away in very small compass when not in use. It is made with or without a folding back. The upright screws into a socket countersunk in the floor of the tonneau, and the seat proper screws onto the top of it; plain, they list at \$10 each, and at \$12.50 with folding backs. This firm is also the maker of the "sterling" mica spark plug and the Cadillac mica cores, designed particularly for use in the single cylinder cars of the latter make. Beside this, they manufacture acetylene gas headlights and generators, or "gas lamp" outfits, which are made in four sizes to suit the needs of any type of car, small or large.

Standard Lamp & Manufacturing Company, 43 South Canal Street, Chicago, Ill.—Lamps and searchlights, the former both for oil and acetylene, for all auto purposes, sums up the showing of this firm. One attractive novelty is a gas tail light in a rather odd and compact form, and designed to be used in connection with a generator or pressure tank. In addition to a complete range of headlights and searchlights in many novel forms and combining numerous ingenious improvements, they show square oil side and tail lamps and also electrics for all purposes, including dome lights for the limousine, as well as a line of lamps in all three classes for marine use, together with their corresponding generators. They are the makers of the "Superior" brazing compound.

Reliable Dayton Motor Car Company, 4515-17 Evans Avenue, Chicago.—This is one of the first of the real "horseless" buggy type of automobile to be specialized for the use of the farmer in the Middle West, and is in consequence already well known. It is equipped with a 15-horsepower two-cylinder horizontal opposed motor of the standard type, and is mounted on high, solid tired wheels front and rear, the power being transmitted by side chains from a countershaft placed well toward the rear, the height of the wheels carrying the chains well out of the dirt and mud. It has square steel axles of full elliptical suspension throughout, steer being by tiller with control levers on tiller post. Complete with top the Reliable-Dayton lists at \$600, and is coming in for no uncertain attention from the rural dwellers, who have come to town with their bank rolls to invest in a car.

Alvin, F. J., Monadnock Block, Chicago.—"Black Hawk" specialties are handled by Mr. Alvin, those exhibited including the "Black Hawk" dry cells, specially constructed to give high amperage and potential with great recuperating powers, and are made in three sizes and for various uses, listing at 35 to 80 cents each. Under the same title there are shown lines of battery connectors and ammeters and sundry other specialties pertaining to ignition.

J. H. Sager Company, F
Sager flexible springs and firm is showing the new skidding and enable a car faces. They are warrant simple and durable, and They list from \$7 to \$12 for tires and wheels, and extra placement, which is easily

Cullman Wheel Company, Chicago.—Beside being agent Whitney lines of chains, the of sprockets for automobile Cullman spur differentials. types for every conceivable either block or roller chain.

Hine-Watt Manufacturing Chicago.—Columbia lamps made by this company, who searchlights in a variety of at noted for their simplicity at state, "They are made on home

REPRESENTING THE COMMERCIAL SIDE A

Biddle-Murray Manufacturing Company, Chicago.—Though trucks made by this firm have been in use in this city for some time past, they were revealed for the first time at a show during the present week. The exhibit consists of a three-ton stake type of truck, although experience has shown that its capacity is considerably in excess of its nominal rating. The power plant consists of a standard four-cylinder vertical motor, mounted well forward, so as to come beneath the driver's seat; the transmission is by means of a selective type of sliding gear, with a final drive through heavy side chains, the motor, changespeed gear box, differential and countershaft all being mounted on a narrow, heavy frame of girder section steel extending the whole length of the car, while the load platform is carried on a separate and independent frame. The front axle is of I-beam section and the rear is a square bar of steel, the brakes being located in drums on the driving wheels; semi-elliptic springs of generous proportions constitute the suspension. As an illustration of what this truck is capable, it may be said that it has delivered a load weighing 6,500 pounds a distance of nine miles in 55 minutes total running time, which gives an equivalent of 29 1-4 ton miles at a total cost of 4 cents per ton mile, figuring the driver at \$3 per day, fuel \$1 per day, lubricating oil 60 cents, and tire wear per ton mile, 2 cents—an unusually creditable showing, and one that reveals in no uncertain manner the possibilities of this form of transportation.

Rapid Motor Vehicle Company, Pontiac, Mich.—This concern has devoted its attention very largely to the production of the gasoline-driven type of sightseeing car, or "char-à-banc" as the Frenchman puts it, and are not exhibiting some of the types they build at the show where they are located in a prominent position in the First Regiment Armory, but also have them running around the streets of the city to good purpose. They are all equipped with a standard power plant, of which the double-opposed horizontal motor, in an accessible position under the center of the chassis, is the chief feature. They are not strangers to the New York streets, either, as several of them have been in operation by the sightseeing enterprises of the metropolis for some time past.

Mitchell Motor Car Company, Chicago.—Grouped with the touring cars and other pleasure vehicles made by this company, is one of its medium capacity trucks, which has the distinction of being the only car of its kind on the main floor of the Coliseum, if the special auxiliary fire department wagon, with its shining brass chemical fire extinguisher tanks, shown by the Knox Automobile Company, is excepted. The makers of the Mitchell cars are not new entrants into the field of business wagon building, and it is evident that the experience they have had with vehicles of this type, as well as the close study they have devoted to the problem during the year or two that they have turned their attention in this direction, has stood them in good stead; their truck is not only a model of what this form of car should be, in that it combines the maximum of carrying capacity and room for loading with a minimum of machinery and dead weight, but it has also shown what it can do in long and extended service under severe conditions.

Knox Automobile Company, Springfield, Mass.—Though fire-fighting is hardly to be termed commercial, it is a most important field—the most important, in fact, and the marvel is that the possibilities of the motor vehicle for this service have not been realized sooner. With its exhibit of pleasure cars, the Knox Company is showing the auxiliary fire department wagon that has made Springfield, Mass., famous for its celerity in nipping incipient conflagrations in the bud, so to speak, and it is hardly necessary to add that this part of the exhibit is coming in for the very generous share which its novelty and importance merit.

Logan Construction Company, Chillicothe, O.—This concern is exhibiting in connection with its wide range of cars for pleasure use one or two types of commercial vehicles that are representative of the numerous forms which they build for business purposes, running all the way from the lightest class of high-speed delivery wagons, through medium capacity trucks, to those of the heavy order capable of carrying large loads at a very low rate of expense when compared with the same service under ordinary conditions.

FISK PRESENTS A NEW REMOVABLE RIM.

The old method when a tire emitted that unpleasant hissing noise indicative of a puncture, was to jack up the car, struggle heroically with the outer shoe, withdraw the air chamber and either repair it or replace it by another. The new method changes all that. With the latest Fisk device, when a tire has to be changed the car is jacked, bolts unscrewed, the deflated tire slipped off, another complete and fully inflated tire taken from its bracket, slipped on, the bolts screwed up, and in less time than it takes to tell it the auto is moving again. When the garage is reached the punctured tire is repaired, mounted and inflated ready for future service.

This Fisk removable rim, the latest production of the Fisk Rubber Company, of Chicopee Falls, Mass., an illustration of which is shown, consists of a specially constructed removable rim, to which any tire may be attached. The road wheel has a special steel rim, one edge of which is flanged to provide an abutment for the tire rim, the other edge being beveled to provide a recess for an expanding ring. The felloe

FISK DETACHABLE RIM WITH AND WITHOUT THE TIRE.

and expanding ring are pierced at intervals by bolts fastened so that they cannot fall out or turn. On the removable rim is a thickened center portion to provide a locking point. When the removable rim with its tire is placed in position the nuts are tightened, the ring expands, holding the rim tightly in place.

WELCH MAKES PROFITABLE FLORIDA RUN.

JACKSONVILLE, Fla., Feb. 4.—It is a pretty tough road that struggles over sand and through hammock land between here and Ormond—115 miles of the veriest apology for a highway. L. H. Perlman, the New York representative of the Welch Motor Car Company, was a prominent participant in the Ormond-Daytona meet, and on the return to Jacksonville he demurred at express charges of \$250 to get his American championship winner here in a hurry to get it on the Clyde Line boat for New York. Therefore he resolved to tackle the alleged road. The Welch left the Ormond garage at 5 A.M., and at 10:40 A.M. the sturdy car reached the steamer dock, 5 hours 40 minutes for the trying run and saving quite a few dollars for gasoline. Mr. Perlman is pleased with Florida, but like many others believes that the State should immediately begin the construction of through trunk roads, which will be the greatest investment ever made by the commonwealth and the means of bringing many automobilists to the "Land of Flowers" for the winter.

ATLANTA, GA., HILL CLIMB ON FEBRUARY 22.

ATLANTA, GA., Feb. 4.—After a long period of inactivity the automobilists of Atlanta have at last bestirred themselves and are now making plans for a hill climb—the first ever held in Atlanta—which will take place February 22.

The entries will be divided into classes and a special cup will be offered for the best record made in each class. It is also probable that there will be a free for all event for which a special cup will be offered.

FUEL TEST SUCCESSFULLY ENDED.

BOSTON, Jan. 30.—The three Maxwell touring cars, used by the Maxwell-Briscoe Motor Company, of Tarrytown, N. Y., in its test of the comparative merits of gasoline, kerosene and denatured alcohol as a fuel for automobiles, completed their trip from New York to this city this afternoon when they stopped in front of the clubhouse of the Bay State Automobile Association on Dartmouth street. The observers included S. Y. Beach, of the *Scientific American*; H. S. Sawyer, of the Automobile Club of America; John P. Slack, W. F. Schultz, and N. S. Dorley. Messrs. Beach, Sawyer and Schultz had charge of the compilation of data concerning the trip. H. A. Grant, who had charge of the test, said that when the data were worked out there would be made available much information of great value concerning the merits of the three hydro-carbons used in the test.

THE NON-STOP THOMAS PERFORMER WHICH ERNEST KELLY AND JOHN COWLING ARE DRIVING ABOUT CHICAGO DURING THE SHOW.

PITTSFIELD PRODUCES A NEW MAGNETO.

The Pittsfield Type F-2 high tension magneto just placed on the market by the Pittsfield Spark Coil Company, is one which for careful workmanship and correct design occupies the highest position. It is provided with distributor and advance and retard saprk lever. The distributor is designed in a manner to insure

NEW PITTSFIELD HIGH-TENSION MAGNETO.

against short circuiting and perfectly excludes dust, water, and moisture. The insulation in the distributor is of ample proportions and when the housing is screwed on it is rendered hermetically sealed. Very ample connections are made from distributor to plugs. The rotating part of the distributor, provided with Hess-Bright ball bearings, consists of the secondary shaft on which is mounted the secondary gear, and into which is fitted the insulator. On this is mounted the distributing brush holder provided with a carbon brush for contact. Best laminated iron is employed for the armature with two sets of windings, primary and secondary. The armature rotates in Hess-Bright ball bearings and is provided with a collector ring from which the current is collected by a carbon brush and delivered to the make and break at the low tension end of the machine on the armature shaft. At the high tension end is mounted the pinion which drives the rotating part of the distributor. The high tension end of the armature

shaft is bored its entire length to receive the rubber insulation through which is threaded the high tension lead from the secondary winding of the armature connected to the brass sleeve of the brush holder. Specially selected imported magnet steel is used for the magnets. The condenser has also received careful attention and is enclosed in an aluminum case. Simplification has been sought in the make and break apparatus, and all working parts are made of tool steel hardened and tempered. The platinum contact points are easily adjustable or can be readily removed and replaced.

TRADE PROSPECTS IN GRAND RAPIDS.

GRAND RAPIDS, MICH., Feb. 2.—The general trade in automobiles in Grand Rapids promises to be very active this year. Already there are seven large agencies in place of four last year, and two of these have more than doubled their floor space. The city now has four automobile manufactories, each making only high grade machines, one of them, just commencing, claiming many new features. No more luxuriously appointed cars are made in the country than are being manufactured by the Harrison Company, the Austin Automobile Company, and the Meenges Motor Company. The other manufacturers, the Couple-Gear Freight Wheel Company, confine themselves to the making of five-ton trucks. The Harrison automobile works is an outgrowth of the Harrison Wagon Works, and has been running two years.

The Meenges Motor Company is a new concern. Albert Meenges was at first employed by the Harrison people, but having obtained some new patents, he is now starting in the business of manufacturing for himself. He has temporary quarters, and thirty men at work. The car is to be a 100-horsepower machine, seating five to eight persons, and will cost from \$5,000 to \$7,000. One of the complete machines will be on exhibition within the next ten days. Some of the good points claimed for the Meenges are, that it will not be necessary to crank, it will be ignited by electric lights, and in the winter will be heated from the exhaust. In addition, the engine, instead of being attached to the frame of the car, is made to rest on coiled springs, it has a new transmission on the rear axle, and a direct drive on each speed.

The Couple-Gear company manufactured twenty-six trucks last year, but expect to work up to their full capacity this year, of one five-ton truck per week.

The strongest local organization here is the dealers' association which has just been formed. It has in view several reforms, one of which is a change in the ordinance requiring that cars travel at the rate of 8 miles an hour in the business section, even though it is up hill. Another thing desired is to get the Legislature to pass a law requiring every vehicle traveling after dark to carry a light both in front and rear to avoid accidents. It is the intention to get the City Council to act on this first, and after that induce other city governments in Michigan to join in the movement and induce the Legislature to take the same action.

STORY OF THE DEVELOPMENT OF THE WHITE STEAMER PICTURESQUELY TOLD BY EACH

WITH THE TRADE IN PITTSBURG.

PITTSBURG, PA., Feb. 4.—A busy season is ahead for automobile salesmen and firms in and about the Pittsburg district. Inquiries are double what they were last year at this time and in many instances early deliveries are being sought. Not only is the touring car attracting attention, but the motor for commercial purposes is being rapidly pushed to the front all through this district.

Although the district abounds in hills, yet the commercial vehicle is forging rapidly to the front. Several additions to the commercial line of trucks in the Pittsburg district were made last week.

The Hotel Schenley has established an automobile service between the hotel and all depots. The service is rather attractive and other hotels are looking with favor upon the scheme. The Schenley has a large Columbia car in service.

Six automobiles are to be purchased by the city of Pittsburg at a cost of \$30,000, and a garage at a cost of \$21,000, according to an ordinance which has passed the Select Council. These cars are to be purchased for park purposes. The idea is to buy six cars with a seating capacity of twenty each for touring the several parks of the city, mainly Schenley and Highland.

Large additions are under way at the garages of the Winton and the Liberty. They will be completed within six weeks, favorable weather prevailing, however.

NEWCOMERS IN THE PHILADELPHIA TRADE.

PHILADELPHIA, Feb. 4.—A new local concern, with the euphonious title of the Zim-Kel Motor Car Company, Inc., has just been formed to handle the Pungs-Finch car in this city. The new concern is capitalized at \$25,000, and the incorporators are Frank G. Zimmerman and Thomas F. Kelly, both well known in theatrical circles here. Quarters have been secured at 320 North Broad street.

The Williamson Motor Company, a West Philadelphia concern whose motors and marine engines are rapidly coming to the front, has established a New York branch to look after its export business. The factory at 812 South Thirty-ninth street, has been greatly enlarged and the adjoining premises secured and fitted up as a garage.

The Scull-Morris Motor Company, with salesrooms at 258 North Broad street, was established last week to handle the Aerocar and Acme in this city and adjacent territory.

The National Supply Company, 1630 Market street, has secured the local Orient Buckboard agency.

The Daimler Company has just closed with Fraser & Reynolds, 214-220 South Twenty-third street, to handle the American Mercedes in this city.

Brooklyn desires an automobile show. Claremont Avenue Rink is suggested as the place in which to hold it, and the week of March 18 proposed as date.

DIAMOND PRESENTS NEW ANTI-SKID.

A new anti-skid tire has been produced by the Diamond Tire Company, of Akron, O. Great care has been exercised in the design and workmanship of this tire and strong claims are put forth as to its resistance to skidding and also its strength to withstand the terrific strains to which a tire of this nature is subjected. Four parallel rows of steel studs are attached to the tread of the Diamond anti-skid tire, and by a special process are secured to extra piles of fabric within. No leather is used, but the fabric employed is manufactured to specifications calculated to meet to the best advantage the severe requirements of the office it performs. This new tire was shown to the public for the first time at the Diamond company's stand at the Chicago show, where it attracted considerable attention and much favorable comment. Nearly all types of American tires were on exhibition at the Diamond stand, including the Diamond Quick Detachable, Diamond Fisk type and others. The exhibit was a representative one.

DIAMOND ANTI-SKID TIRE.

TRADE ITEMS FROM TOLEDO.

TOLEDO, O., Feb. 4.—At its annual meeting the Toledo Auto Touring Car Company decided to sell \$10,000 worth of treasury stock, and with the proceeds purchase two sight-seeing touring cars, each having a capacity of 18 passengers. The present plan of the company is to operate all three cars on Sundays and other fete days, and during the remainder of the time to operate two, holding one in reserve. The concern elected the following directors: President, John Stolberg; vice-president, John C. Heidelberg; secretary and treasurer, Frank G. Crane.

The Union Supply Company, which for several years has operated a bicycle and rubber goods supply store on Superior street, has increased its capitalization, and in the future will also handle automobile supplies and auto accessories. J. G. Swindeman is president of the company.

According to W. S. Cranmer, one of the representatives of the Pope-Waverley Automobile Company, Toledo uses more electric automobiles than any other city of its size in the United States. He also says that the city has the finest and best equipped electric garages between New York and Chicago. His company sold 60 machines in Toledo last year.

YEAR'S MODEL SINCE 1901. COMMENCING AT LEFT AND READING SUCCESSIVELY TO THE RIGHT.

NEWS AND TRADE MISCELLANY.

The capital stock of the Perfection Spring Company, of Cleveland, O., has been increased from \$20,000 to \$50,000. Automobile springs are manufactured exclusively.

The R. H. Smith Manufacturing Company, of Springfield, Mass., has secured a patent covering the name of its speed indicator, the Springfield Motometer.

"The Bigness of Little Things," a Winton booklet, dealing with the importance of small matters in automobile manufacture, has been in such demand that a new edition has been issued.

A removal has been made by the Franklin Automobile Company from 1218 Michigan avenue, Chicago, to new and more commodious premises at 1450 Michigan avenue.

Realizing the need of especially careful design in the engine, the most vital part of the automobile, the firm of Illmer & Co., of Cincinnati, O., has entered the field of automobile engine design and offers expert service in this line to automobile builders.

John D. Rockefeller had his new Packard car equipped with the Truffault-Hartford shock absorber at the Hartford Suspension Company's factory this week. Mr. Rockefeller has used these shock absorbers on all his cars for the past three years.

The Hartford Automobile Parts Company's factory was slightly damaged by fire last week. The outbreak was confined entirely to the company's offices and assembling rooms, and did not interrupt the manufacture of the Hartford Universal joints to any extent.

A night force of workmen is now being employed by the Auto Parts Company, of Muncie, Ind. Only a short time ago the company removed from its old position on North Walnut street to Proud street and the L. E. & W. Railway. Indications are that additions will have to be made to meet with the ever-growing business.

The Okey Motor Car Company has been incorporated at Columbus, O., with a capital stock of \$25,000, to manufacture automobiles. The new officers of the company are Campbell M. Chittenden, president; A. G. Walton, general manager; F. R. Shinn, secretary and treasurer; Perry Okey, engineer.

A new branch has been added to the business of the Brooklyn Motor Car Company, in the shape of a large supply department. The store next to the one occupied at 1384 Bedford Avenue has been secured and will be so altered that the two will make practically one. E. P. Archer will have charge of the new department.

The Canada Cycle & Motor Company, of Toronto, has purchased in Ottawa the property extending from Sparks street to Queen street, on which is situated the stone building formerly occupied by the Perkins foundry. The building will be fitted up as a garage and show-rooms, and a repair shop will be built on Sparks street. The premises will be opened in the spring.

The Winton Company announces that it will shortly open its own branch house in Detroit. From this announce-

ment it is evident that the company finds the branch house plan profitable, for such establishments have been conducted for several years in New York, Boston, Philadelphia, Cleveland, Chicago and London; in addition a Winton branch was opened in Pittsburg about a year ago.

Baron Taranauke Furukawa, one of the leading financial and mining magnates of Japan, after covering the field of automobiles, has placed his order for a 50-horsepower Matheson touring car, which he will use in his extensive mining travels in his country. He is taking a course in mining engineering at Columbia University to qualify himself in regard to everything concerning the mining interests which he promotes.

The J. S. Bretz Company, of New York City, American agents for the firm of Fichtel & Sachs, Germany, have just received from the parent company a report of the great success with which the F. & S. annular ball bearings are meeting in Europe. Although very large manufacturers of ball bearings of other styles, it is only five years since Fichtel & Sachs gave their attention to the production of the annular type of bearings. In that period their annular bearing business has grown to enormous proportions, and they are to-day one of the largest producers of this class of goods.

At the annual meeting of the stockholders of the Witherbee Igniter Company, held at the company's New Jersey offices last week, the following directors were elected: Wm. Barret Ridgely, Albert A. Blow, Edward Ridgely, Allmand B. Elliott, David F. Plahn. The officers of the company for the current year are: Wm. Barret Ridgely, president; Allmand B. Elliott, vice-president and electrical engineer; Alfred S. Watson, secretary and treasurer; Albert J. Fisk, general manager. Thomas S. Witherbee, the former president of the company, is no longer connected with it in any way. The company will continue under its present name, the Witherbee Igniter Company.

Six cars per week—or one each day—are being shipped from the works of the Lozier Motor Company at Plattsburg, N. Y., and during February and March the output will be increased to eight per week. As the Lozier Company claim to make practically every part of the car from rough stock in their own works, this is an unusual product for a car of its class. The shipping facilities in the Lozier works are unexcelled. The railroad company has built its tracks into the large building used for assembling. A traveling crane operated by compressed air has a ten-ton capacity, and one man can, by its aid, carry a complete car from one part of the building to another with the greatest ease.

A novel and most effective method of testing transmissions and gears is that in vogue at the plant of the Electrical Vehicle Company at Hartford. A chassis is mounted on blocks, and the transmission set secured to its supports just as it is in the finished car. The transmission is coupled direct to a water friction brake. An electric motor, which revolves at a speed of from 500 to 1,500 revolutions per minute, is mounted in approximately the same position as that of the engine in the finished car. This motor is

coupled direct to the transmission. The motor is then run and the transmission set working against the resistance developed by the water brake does practically the same amount of work intended for it in the complete car. The different speeds are effected in the usual manner by change gear lever. The various speeds of the motor and transmission afford a most practical test of efficiency. So great is the friction developed in the brake that a circulation of city water working at a pressure of 80 pounds is necessary to keep the brake cool.

NEW AGENCIES ESTABLISHED.

The St. Louis cars will be handled in Kansas City, Mo., and vicinity this season by Cowie & Pierson, 1413 Grand avenue.

The Cook & Stoddard Co., of Washington, D. C., has secured the agency for the Darracq in that city. It is interesting to note that this is the first foreign car agency to be placed there.

The Dupont Garage Company, of Washington, D. C., has been appointed agent for the Waltham-Orient. The Rambler and Cleveland will be handled in the Dupont garage by George P. Sacks.

Bond Brothers Company, recently incorporated and located at 10 Columbus avenue, in the Motor Mart, Boston, has taken up the agency for the Deere car, manufactured by the Deere-Clark Car Company, of Moline, Ill., for the Boston territory. The Bond brothers are well known in the New England local trade.

PERSONAL TRADE MENTION.

E. H. Gato, the wealthy cigar manufacturer of Havana, has placed an order for a Winton X-I-V.

Charles B. Shanks, general sales manager of the Winton Company, will shortly go to Florida to recuperate from the la grippe atmosphere of the show season.

Charles S. Monson has been appointed manager of the Detroit branch of the G & J Tire Company, of which he has been acting manager for some months.

W. W. Partridge, a native of Massachusetts, and until recently connected with the insurance business, has removed to Cleveland and entered into the automobile line with Henry Moore, local agent for the Stoddard-Dayton car.

At the close of the automobile show Charles H. Martin severed his connection with the Knox Automobile Company, of Springfield, Mass., and has formed a partnership with Cecil H. Taylor, as consulting engineers for commercial automobiles. Their address is 29-31 West Forty-second street, New York.

RECENT INCORPORATIONS.

Conover Motor Company, Paterson, N. J.; capital, \$20,000. Incorporators, Edwin K. Conover, Alfred W. Watson and Samuel J. Watson.

American Pump and Motor Company, Chicago, Ill.; capital stock, \$500,000. Incorporators, Perry A. Thompson, Herman C. Straube and James M. Lynn.

Rainier Motor Car Company of Illinois, Chicago, Ill.; capital, \$20,000. To manufacture and deal in automobiles. Incorporators, John T. Rainier, Paul N. Lineberger and Edward Q. Gardner.

THE AUTOMOBILE

VOL. XVI.

NEW YORK—THURSDAY, FEBRUARY 14, 1907—CHICAGO

No. 7

JAMAICA AS JUST SEEN BY AN AMERICAN AUTOIST

ALL of us have long known that somewhere in the West Indies is an island called "Jamaica." As to just where it is and what it is like, few people—except those few who indulge in winter tropical trips—ever knew or cared until one day last month the cable brought the news that a disastrous earthquake had occurred there and had practically wiped out of existence the city of Kingston, the capital of the island. For two or three days we read of the disaster and of the relief measures being adopted, and then were stirred by the boorishness of Swettenham, the Governor of the island, who treated a representative of this government in such an unseemly manner. The attention of automobilists was attracted to a line in the news from Kingston to

the effect that "an automobile was doing splendid service in the work of relieving the sufferers." With the return to this country of Dr. William F. Bacon, of York, Pa., and his companions, not only are we informed concerning the part which the automobile played after the catastrophe, but also we learn that Jamaica has a claim upon the attention of autoists, such as few other localities possess.

Dr. Bacon, with three friends, sailed for Jamaica on the first boat which left New York after the earthquake. He was commissioned to find the body of one of his patients whom the first dispatches reported as being killed. On arriving at Port Antonio, on the north shore of the island, four days later, he re-

THE PRINCIPAL HOSPITAL CAMP IN THE OUTSKIRTS OF KINGSTON.—WHITE STEAMER STARTING ON ONE OF ITS MANY TRIPS.

THE U. S. CONSUL DID MUCH DESPITE THE IRASCIBLE GOVERNOR.

ceived the reassuring news that his patient was unharmed, and had, in fact, started for the States. And right here it should be made plain that the action of Governor Swettenham was in no way typical of the attitude of the other insular officials. No sooner had the Mayor of Port Antonio heard that a physician had arrived, than he came to see Dr. Bacon and besought him to lend his aid to the local physicians.

"I will do anything you want," replied the doctor, "and go anywhere you say."

"We have no accurate knowledge of conditions in the interior of the island," replied the Mayor. "The negroes report great loss of life in the landslides which occurred in the mountain districts."

"Have you a motor car handy?" queried the doctor, having in mind the necessity of quick transportation.

"The only car in town is Victor Camp's White steamer," replied the Mayor. "Camp's machine has been busy ever since the earthquake, but I guess he will accommodate you."

The Steamer Was a Time-saver.

In less than two hours after the doctor landed, he and his friends were on their way across the island in Camp's "steamer," with the owner at the wheel. As soon as they reached the mountain districts they found the negroes in a state of wild trepidation. Monstrous rumors were afloat regarding conditions, not only in the island, but also in the outside world. For example, one negro, the owner of a prosperous plantation, asked if it was true that the Isthmus of Panama had sunk into the sea. Actual loss of life or limb caused by the landslides had been very slight,

ONE OF THE EARTHQUAKE VICTIMS RECEIVING MEDICAL ATTENTION.

but still there was plenty of work for the doctor. Every physician in Jamaica had gone to Kingston immediately after the earthquake, and the rest of the island was entirely without medical aid. Mr. Camp's automobile carried two Red Cross flags, and their significance was appreciated by the natives. At every little cluster of huts some invalid would be brought forth for attention. The reverence of the simple folk for the doctor was very affecting. The families of the sick persons would approach the car on their hands and knees and beg that the doctor might effect a cure. Night came on while the party were engaged in their beneficent work, but such is the brilliancy of the tropical moon that the doctor continued to administer until his supply of medicine was exhausted. The car had started with a well-filled medicine chest strapped behind on the luggage carrier, but even this supply proved insufficient.

Finally, the tourists reached the Constant Spring Hotel, six miles inland from Kingston, and here they spent the night. In the morning Dr. Bacon and his companions reported for duty at the government hospital at Kingston, and here their labors began anew. The tired and overworked hospital staff had an immense range of territory to cover. Every day they had to make the rounds of the refugee camps and new cases in the outlying districts were daily requiring treatment. No means of transportation had been at their disposal, except donkey carts. Mr. Camp immediately put his car at the disposal of the hospital corps, and

RESIDENCE OF THE GOVERNOR WHO DECLINED AMERICAN AID.

thereafter every member of the staff was enabled to complete his work in about a third of the time previously required, with a consequent gain in the amount of time available for much-needed rest. Furthermore, as one of the staff expressed it, "A ride around the city in that car is as refreshing as a two-day furlough." It was also a great treat to the faithful Red Cross nurses, who had labored unceasingly since the earthquake, to go to and from their work in the swift and silent machine. Then there were medical supplies of all kinds to be distributed, and in this work, too, the machine proved itself just as useful as it did at San Francisco.

Finally, after four or five days of constant effort, the medical situation was brought into such satisfactory shape that Dr. Bacon and his party felt that they could, with justice, think of returning. Bearing with them an official letter of appreciation from the hospital authorities, the tourists started back toward Port Antonio, proceeding in a leisurely manner, and by a circuitous route, observing meanwhile the character of the country and of its inhabitants, particularly as regards the desirability of the island from the automobilists' point of view.

Jamaica Has Excellent Roads.

Naturally, the roads first commanded attention. It will be a surprise to people in this country to learn that in far-off Jamaica all roads are level and built of stone, and they reach every nook

EAST STREET, ONE OF KINGSTON'S THOROUGHFARES AS IT LOOKED AFTER THE EARTHQUAKE HAD DONE ITS DESTRUCTIVE WORK.

and corner of the island. The material used is a white stone, which is soft and crushes readily. This stone is very porous, and the heavy tropical rainfalls disappear from its surface almost instantaneously. Furthermore, this style of road is very easy on automobile tires. Mr. Camp's White has been over 10,000 miles on one set of tires, and he expects to get from them several thousand miles more of service. It is doubtful if any road in this country can compare with those which prevail throughout Jamaica. The entire interior of the island is very mountainous in character, yet the ridges are crossed by easy grades, and it has not been thought necessary to build "water-brakes," the bane of the autoist.

Another important point which the tourist noted was the security of life and property in

FIRST SHOCK STOPPED THE CLOCK.

the island. Jamaica has been a peaceable English colony since 1638, administered by an officer appointed by the crown. The English law, as well as the English language and customs, prevails in the island, and respect for the law is absolute on the part of the most ignorant inhabitant. The island is well patrolled by native constabulary, and the records of the local courts show that almost the only offenses are petty larceny cases.

An overwhelming preponderance of the population of the island is negroes, the descendants of slaves imported from Africa. During the last century there were brought from India a considerable number of coolies, who maintain their original religion and customs, and do not intermarry with the negroes. These interesting people are found in small

TROPICAL FOLIAGE IN PRODIGAL QUANTITIES IS FOUND IN THE INTERIOR OF THE ISLAND, WHICH CONTAINS EXCELLENT ROADS.

IT IS DELIGHTFUL ALONG THE SHORE ROAD BETWEEN PORT ANTONIA AND ARMOTTA BAY.

colonies throughout the island. Both the above classes are honest folk, and their attitude toward the automobile tourist is one of profound respect. The natives live in little bamboo huts, which are so well distributed over the island that one or more of these little homes is almost always in sight.

The roads lead past groves of banana trees or through orange or coffee plantations, and the numerous forms of strange tropical plants are a constant source of wonder and delight to the tourist. In the mountain districts the road very often parallels some beautiful stream with innumerable waterfalls. Every visitor to Jamaica, starting with Columbus, who visited the island in 1494, has spoken in unbounded praise of its great natural beauties.

Jamaica Has a Sensible Auto Law.

Jamaica has a motor-vehicle law, and it is one which the legislators of our States might well take as a model. To those who have had experience with our State Legislatures, it is a genuine surprise to learn that distant Jamaica should actually have in force at the present time a law such as we think of only as an ideal which may or may not be realized in years to come. The only speed limit stipulated in the Jamaica law is that "No person shall drive a motor car on the public highway recklessly, or negligently, or at a speed or in a manner which is dangerous to the public." The remaining provisions of the law provide simply for registration, for lamps, for "a horn or other instrument for giving warning," for the licensing of drivers, and for stopping in case of accident.

In still another way the Jamaican government has shown a more friendly interest in automobiles than have our State governments. Within the last two months the insular authorities have issued a complete and detailed guide-book of the roads of the island, giving the mileage and description of all the turns. In compiling this work, they used as a model the guide-book compiled for last year's A. A. A. tour, with the style of which most automobilists in this country are familiar. Efforts are being made by the Jamaican automobilists to attract American auto tourists.

As regards the destruction wrought by the earthquake, it should be stated that the damage was confined to Kingston and to the immediate vicinity. Before another year has elapsed even that city will again present its wonted commercial activity. It was, before the earthquake, the largest city in the British West Indies, having a population of over 55,000.

Although the climate of Jamaica is salubrious all the year round, the best months to visit the island are from December to March, inclusive. Tourists will find at Port Antonio as good a hotel as in any of the summer resorts of this country, and in many of the other coast towns are hotels which cater to the tourist traffic. The island may be reached from New York City by any one of three steamship lines; the Hamburg-American, the Royal Mail Steam Packet Company, and the United Fruit

Company. Port Antonio is about 1,440 miles from New York, and the voyage is made in four or five days. Within 24 hours after leaving New York, the traveler is in the midst of the Gulf Stream and is enjoying delightfully warm and balmy atmosphere.

Arriving at Jamaica, the custom-house formalities take only a few seconds, although on his return to his native country the traveler must be prepared for a long array of formalities.

From the foregoing description—of the good roads, of the friendly attitude of the government, of the attractions of a tropical country, and of the accessibility of the island—it is evident that Jamaica well merits the favorable attention of the autoist.

RANCHMEN TAKING TO THE AUTO.

FORT WORTH, TEX., Feb. 11.—Automobiles as means of travel to and from ranches located at some distance from railroads are becoming more and more popular in this State every day. A number of the large ranchmen of West Texas have now almost given up the pony in favor of the automobile. Trips over the ranches can be made for miles, the ground being smooth enough in most places for the machines to travel anywhere. Speed and comfort are both much greater than formerly.

A TYPICAL MOUNTAIN ROAD. FRINGED WITH BANANA TREES AND A WEALTH OF FOLIAGE.

CHICAGO'S SHOW WAS SUCCESSFULLY GRATIFYING

CHICAGO, ILL., Feb. 9.—With an attendance that crowded both Coliseum and Armory to capacity to-night the Chicago show ended its successful eight days and nights of telling the Westerners about the 1907 automobiles. It would appear from the attendance figures and numerous sales—especially the latter—that as long as shows continue there must be a national event in Chicago as well as in New York City. Manager Miles certainly sprang a surprise in the artistic dressing which he gave the two buildings, and to the exhibitors there was more gratification in the matter of attendance of agents from the middle and extreme West.

Herewith are some of the expressions of opinions from members of the N. A. A. M. Executive Committee:

Thomas Henderson, Winton Motor Carriage Company.—"I'm a veteran of three shows this season, so to speak. I was at Olympia in November and at the Garden in January, but I haven't seen anything to surpass this. I think it's the most creditable effort ever made in this country, whether in Chicago or elsewhere, and the thing that impressed me most forcibly about it is the fact that it is more in keeping than others have been. There is an atmosphere about it that was lacking at the Garden. It typifies the automobile more to my mind than the New York show did."

W. E. Metzger, Cadillac Motor Car Company.—"The Chicago show has been a great success, typical of the West, which is buying automobiles in far more generous quantities than ever before. And the Westerner takes a whole-souled interest in the auto which he makes no effort to conceal. He is out to see and take note, which is probably one of the reasons why the Western show is such a popular affair."

S. T. Davis, Jr., Locomobile Company of America.—"The Chicago show must be set down as one of the greatest benefits to the industry. The numerous sales tell their own story where the business end of the show is concerned, and as for the popular side of it, anyone who visited the Coliseum or the Armory any time during the week hardly needs to be told what a success the show has been from that point of view."

Benjamin Briscoe, Maxwell-Briscoe Motor Company.—"It has New York show beaten a mile, to put it in the vernacular, and my honest opinion is that this country has never seen

anything to equal it, much less to surpass it. It certainly does the industry credit and results in benefit that is felt the remainder of the year. This is the biggest thing Chicago has ever done, and that means the biggest that has ever been carried off in this country, to my way of thinking."

Ezra Kirk, E. R. Thomas Motor Company.—"I have attended shows of different kinds for the last ten years or more, but I have never seen anything in the line of an industrial exhibition that came anywhere near equaling this. It has all others that I can recall totally eclipsed from every point of view, and that is saying a great deal. It took the automobile as an incentive to show what could be done in that way, but in this case it has surpassed its own record manifold."

Windsor T. White, the White Company.—"Whether considered from the amount of business accomplished, the decorative setting, or the attendance, the Chicago show has proved a most gratifying success. It is by far the biggest thing ever attempted in the way of an industrial exposition by any organization, no matter how large or influential, and doubtless the present event will go down into history as having set a standard that it will be found difficult to surpass."

C. C. Hildebrandt, Stevens-Duryea Company.—"The show has undoubtedly set a high-water mark in every respect. Shows can hardly be bigger until buildings increase in size, and it is doubtful if there will ever be one roof capable of sheltering the industry, but this demonstrates what can be done both in quantity and quality. In my opinion there has seldom been a more creditable event carried off anywhere in this country."

William R. Innes, Studebaker Automobile Company, was of the opinion that the Chicago show was relatively an event of far more importance to the two-thirds of the country west of it than the New York show was to the one-third of the country between Chicago and the coast. "It seems to me that the show means more to Chicago than it does to New York, though, of course, I'm not a resident of this part of the country and cannot speak from the viewpoint of one," he added. "It is certainly a great success and more than fulfills my expectations."

A. L. A. M. ENGINEERS ELECT AND DISCUSS

CHICAGO, ILL., Feb. 6.—After the business of the annual meeting, held at the Chicago Athletic Association, and at which A. L. Riker was unanimously reelected president, and W. S. Clarkson continued as secretary, was disposed of, the engineers of the Association of Licensed Automobile Manufacturers and the representatives of the manufacturers who had been invited to attend, took up the discussion of carbureters, particularly with regard to the use of alcohol as a fuel. There was considerable difference of opinion expressed, both as to the availability of alcohol for automobile use as well as on the subject of carburetion generally. Following this there was a discussion on the subject of springs, with which was included a talk on clutches and shock absorbers, but the matter of suspension proved to be one of such absorbing interest that a very large part of the time was devoted to it. Experts from a number of steel and spring manufacturing concerns were present and gave illustrated talks on the subject of treatment of spring metals. It was conceded that the front springs were chief, if not only source of trouble.

During the informal discussion that followed, the fact was brought out that there will be several prominent contenders in the elimination trials for the Vanderbilt Cup this year who have not previously competed, as well as others who competed two

years ago and will again enter, the plans of the builders of the Royal Tourist being the most recent development in this direction. The trend of the discussion indicated that the subject of racing would be considered of far greater importance during the coming year than ever before. As it was not found possible to give the subjects above referred to the amount of time they deserve at the Chicago meeting, the discussion will be continued at the next monthly meeting to be held at the association rooms in March, and this will be supplemented by a discussion of the subject of racing, it being a matter of common knowledge that several high-powered cars are in prospect for this year's Vanderbilt. The following members were present:

Edgar Apperson.	Frank Johnson.	J. S. Worthington.
Elmer Apperson.	G. P. Barrett.	J. H. Jones.
W. H. Little.	J. A. Becker.	G. W. Bennett.
Reynolds Janney.	B. A. Becker.	A. L. Riker.
E. C. Sweet.	John W. Wilkinson.	A. W. Robinson.
F. W. Hawes.	F. M. Nutt.	A. C. B. King.
V. M. Gunderson.	G. N. Mismar.	C. C. Hildebrandt.
G. W. Gunn.	G. W. Haas.	C. H. Halkins.
Charles Clifton.	Robert Jardine.	George E. Sparks.
Daniel Ferguson.	Alden Sampson.	E. P. Chalfont.
Harold L. Pope.	George E. Mitchell.	H. D. Church.
W. G. Gilder.	E. T. Birdsall.	H. E. Coffin.

BRISCOE NOW LEADS THE INDEPENDENTS

CHICAGO, Feb. 7.—At the largest and most enthusiastic meeting in its history, the American Motor Car Manufacturers' Association in annual session selected Benjamin Briscoe, of the Maxwell-Briscoe Motor Company, as chairman of the committee of management for 1907. Mr. Briscoe has been a member of the association since its inception, and last year was chairman of the show committee. His remarkable strides in the motor car manu-

BENJAMIN BRISCOE,
Chairman A.M.C.M.A. Committee
of Management.

ALFRED REEVES,
Re-elected General Manager
A. M. C. M. A.

facturing field have made him one of the most important figures in the industry, the growth of which has astonished the world. James Couzens, of the Ford Motor Company, who has been chairman of the committee of management for two years, declined a re-election. In appreciation of the good work he has done, the association passed a resolution of thanks and elected him an honorary member of the committee.

That the association has been doing work for its forty members during the past year was shown by the report of Mr. Couzens and by the heads of the various committees. The chairman's report showed that the association has nearly doubled its membership during the past eight months, and the list of forty makers now holding membership is certain to be largely increased during the next few months. Optimistic reports were submitted by the treasurer and by the committees on membership, agencies, good roads, and legislation, standardization, runs and tours, freight and transportation, advertising and shows. A general feeling of satisfaction was expressed at what had been accomplished during the Couzens-Reeves administration.

The official report of the meeting contains this paragraph:

"The opinion was universal that the Chicago show being held in February is much too late for general benefits. It is neither a wholesale nor a retail affair, and there were many reasons advanced why it should be changed to November or December. This gathering of strength in favor of early shows (the original idea of which was first put into operation by the American Association) is gathering followers every day. Of course, if the Chicago exhibition was run in November or December it would necessitate a change of date for the Garden show in New York. The Grand Central Palace exhibition in New York last December was such a pronounced success from a business point of view—notwithstanding the talk of decorations, etc., these shows are held primarily for business and to stimulate the interest in automobiling—there seems no good reasons why the affairs should not be conducted in November or December. This will be especially apparent next fall with the fewer changes to be made on the 1908 models. The proof of this reasoning was offered by the report of the December show in New York, which, besides drawing a record number of exhibitors, an unprecedented attendance of agents and retail buyers, permitted a profit dividend of 45 per cent. in addition to an original discount of 20 per cent. to members of the association."

Three members were elected to serve three years on the committee of management: Benjamin Briscoe, Maxwell-Briscoe Motor Company; R. E. Olds, Reo Motor Car Company; H. O. Smith, Premier Motor Manufacturing Company. Roger J. Sullivan, of the Wayne Automobile Company, was chosen to fill the vacancy caused by the resignation of A. C. Newby, of the National Motor Vehicle Company, who asked to be relieved of association responsibilities to give more attention to his business interests.

After the general meeting the business session of the committee of management was held, when plans for an active year were discussed and the following officers chosen: Chairman, Benjamin Briscoe; vice-chairman, R. E. Olds; treasurer, H. O. Smith; auditor, Roger J. Sullivan, and general manager, Alfred Reeves.

It is understood that the American Association had some idea of shortening its name, and several variations were suggested, one of which may be adopted at some future date.

NEXT WEEK'S LOCAL SHOWS IN VARIOUS CITIES

CLEVELAND SHOW WILL HAVE "DOLLAR" NIGHT.

CLEVELAND, O., Feb. 9.—It has been decided to follow the lead set by New York at the Garden in January and have a "dollar night," the general admission during the evenings also being advanced to 50 cents. For the afternoon the admission will be 25 cents as heretofore. The big Central Armory is being tastefully decorated for the show which opens on Monday, February 18, and continues all the week, and improvements are being made in the entrances and the heating arrangements, so that the building will be more comfortable than it has been during previous shows. The conflict with Buffalo did not reduce the exhibitors' list.

ELECTRICAL DISPLAY AT BUFFALO'S SHOW.

BUFFALO, N. Y., Feb. 11.—It has been decided by the officials of the Automobile Club of Buffalo, which conducts the automobile show in connection with the local trade association, to be held in Convention Hall next week, February 18-23, that the principal decorative piece shall be an immense reproduction of the badge of the local club. This electrical piece will contain at least 1,000 incandescent lights and will be 15 feet in diameter. It will extend from the balcony to the girders of the building. In the center

of the hall will be placed a magnificent electric dome, containing about five hundred incandescent lamps of 16 candle-power.

One week from to-night the Buffalo's annual show will open. It has been decided by the committee in charge that the show will open at 10 o'clock in the morning and continue until 10:30 P.M. each night, instead of only afternoon and evening sessions as heretofore. On account of engagements, the show management will not get possession of Convention Hall until next Saturday at midnight, so that in order to open on time Monday morning there will have to be some tall hustling.

WORCESTER'S SHOW PREPARATIONS COMPLETE.

WORCESTER, MASS., Feb. 11.—Frederick N. Prescott, of Boston, chosen by the various automobile dealers of Worcester and the local militia companies to manage the automobile and powerboat show and military carnival to be held in the State Armory here the week of February 18, has completed all arrangements for the affair. The armory will be decorated in tropical fashion, and there will be 60 spaces for exhibits. All of these have been taken, the Worcester dealers receiving the first awards for space, and the Boston contingent taking the remaining space.

AEROCARS FILLED A PROMINENT SPACE AT CHICAGO.

SEEN AND HEARD AT CHICAGO.

One keen-eyed observer found out after considerable investigation that though all connecting rods looked alike, there was a difference. The rods themselves show no variety, there scarcely being a dissenting voice from the drop forging of I-beam section; it is the manner of fastening the big end that differs. In some this is of the usual hinge type and others of the marine type, the latter having numerous advantages, not the least of which is its greater ease and accuracy of adjustment to take up wear.

One of the most instructive sights uncovered by the interested and inquisitive visitor was that of a stump placed beneath the front axle of a car at the Adams Company's booth in the Armory. It graphically demonstrated what 16 inches clearance meant, as the stump was labeled with a sign to that effect, and to the very great majority of those who saw the latter it brought home to them for the first time the real meaning of clearance of any kind. It showed the kind of a road or lack of one that the Adams car could navigate without losing any of its under trimmings or disabling any part of its mechanism.

That Chicago is a man's show was never more strongly evidenced than by the attendance during the afternoon on any day of the show this year. Women there were, of course, but in nothing like the numbers to be found in the Garden at a corresponding hour of the day. During the afternoon at Chicago there was scarcely one of the gentler sex to 20 men, and what made this discrepancy very much more noticeable was the fact that a great many of the women were without male escorts. They came in couples and groups to see the show and these "hen parties" were greatly in evidence at a time when it would be thought there would be more of them. During the evening there was little to distinguish the Windy City attendance from that of New York on the score of representation of the sexes.

Talk at the show after Thursday, or in fact, immediately after the fact that the Deming trophy was missing from the Maxwell booth became public, was the query: "Who pinched Mercury?" As Mercury in just about the size of the missing statuette was in evidence all over the main floor by the score, this was thought to be a joke at first, but this did not prevent the private detectives at the building from holding up everyone with a package at the door until its contents could be examined. The statuette stands about 26 inches high and tips the scales at something like 25 pounds, so that it would not be exactly an easy thing to get away with. It was missed from its accustomed place on the show case flanking the main aisle shortly after noon Thursday. On Friday the press agent found Mercury.

Someone with a head for figures and nothing much else to do, got busy on the show about the middle of the week, and when he got through he had calculated the aggregate and the

THE SIDE LIGHT SHOWED THE HARRISON TO ADVANTAGE.

average power of all the cars shown. There were something like 500 machines in all staged, and he figured that their average power would be approximately 30 horsepower, making the total for the entire show 15,000 horsepower. The term still continues to confuse quite a number of the visitors. After much hesitation a woman approached one of the attendants at an exhibit and asked for an explanation of the term "60 horsepower." "Thank you so much," she said after the matter had been elucidated at length. "We only have one auto in our town, and the horses are not used to it yet. I thought probably 60 horsepower meant it might frighten that many horses a day."

One of the largest pneumatic tires ever manufactured was the star attraction at the exhibit of the Diamond Rubber Company, and the size of this giant of pneumatics certainly made tires of standard dimensions look like the veriest pygmies. Like the shoes and shirts of Brobdignagian proportions occasionally displayed in store windows as "attention attracters," it looked far too big to be real, though it was, as it was a replica of one of a set made for a large limousine built by the Westinghouse Company, and which tipped the scales close to the 6,000 pound mark. The dimensions are metric, and are 1,000 by 165 millimeters, which represent the approximate equivalent of 40 by 6 1-2 inches. The largest American tires regularly made are 36 by 5 inches, so that special machinery was necessary to turn out these monsters. How this greatest of all pneumatic tires looks in comparison with some of the more frequently used sizes—those that are seen every day—is strikingly pictured by the accompanying photograph of it posed with two others, one of which is the smallest size regularly made, 22 by 3, the other being a 30 by 3 1-2 tire, largely used on light-weight touring cars.

BIG DIAMOND TIRE AND ITS SMALLER BROTHERS.

GASOLINE CHEAPEST WITH PRESENT MOTOR

AS a part of the series of experiments being conducted from time to time by H. A. Grant and J. D. Maxwell, of the Maxwell-Briscoe Motor Company, to determine the relative efficiency and commercial value of various forms of fuels, three Maxwell touring cars made the run from New York to Boston,

A HALT BETWEEN SPRINGFIELD AND WORCESTER.

each using a different fuel, on January 28-30, the details of the trip having already been given in *THE AUTOMOBILE*.

The three cars employed for the test were standard Maxwell touring cars of the model of 1907, fitted with a double-opposed horizontal motor, the cylinders of which measure 5 by 5 inches, while the initial compression is 58 pounds to the square inch. These motors are nominally rated as having an output of 16 to 20 horsepower when used with gasoline as a fuel. Each car carried the same number of passengers and equipment, the weights being as follows: Car using gasoline fuel, 2,270 pounds; kerosene, 2,520 pounds, and alcohol, 2,750 pounds. The carbureters were all of the standard type regularly employed on the Maxwell cars, and no special devices were added in the case of those using fuels other than gasoline. No adjustments of any kind were found necessary at any time during the trip, the actual running time of which was 16 hours 20 minutes, and the distance covered 249 miles, giving an average speed of 15.41 miles per hour.

Owing to the heavy going, which was made considerably worse on that part of the route from New Haven to Boston by reason of the snow, which was almost a foot deep for almost 150 miles of the run, the gasoline consumption was unusually great and that of kerosene and alcohol correspondingly so, though it is

probable that the proportion would not differ greatly, the test having been one of sufficient length to permit of forming an excellent idea of the comparative values of the fuels when used in the type of engine now current. The average mileage per gallon of gasoline was 10.1—a good showing in view of the road conditions; of kerosene, 7.4, and of alcohol 6.13 miles.

Every ounce of fuel that was used on each of the cars throughout the entire run was carefully noted by the observers, and these figures, taken in connection with those of the weight of the cars and distance covered, give some very interesting data regarding the cost per car mile and per ton mile for each fuel, these being shown by the appended table, which also gives the total amount of each class used and its cost:

Car.	Weight.	Cost per Gallon.	Total Consumption.	Cost of Fuel.	Cost per Car Mile.	Cost per Ton Mile.
Gasoline	2,270	\$0.20	24.75	\$4.95	\$0.019	\$0.0169
Kerosene	2,520	0.13	33.75	4.39	0.017	0.0139
Alcohol	2,750	0.37	40.75	15.07	0.06	0.0448

Almost twice the quantity of alcohol was required to travel the same distance as with gasoline and almost 50 per cent. more when kerosene was the fuel employed.

Taking the cost of the different fuels into account, the showing is even less favorable where alcohol is concerned, but it must be borne in mind that the engine was not particularly designed to

REPLENISHING THE FUEL TANKS OF THE ALCOHOL CAR.

use this fuel. Thus the cost figures out fully 2 1-2 times greater than that of gasoline and over three times more than that of kerosene, though there is not such a wide difference between the quantity of the latter required as compared with gasoline. Taking these figures as a basis, it is evident that alcohol would have to sell at 22 cents per gallon in order to compete with gasoline at 20 cents, even though used in a specially designed motor.

Many interesting observations were made as to the characteristics of alcohol when used in a gasoline motor, such as the fact that the motor apparently developed a great deal more power on hills than those using kerosene or gasoline by reason of the higher mean effective pressure, particularly owing to the short stroke of the motors employed. With the equipment fitted to the cars it was impossible to cause the motor to knock or pound by reason of advanced ignition, nor could the motor be stalled on a hill.

The chief object of the test was to demonstrate the availability of these fuels for use in the modern automobile motor without the necessity of any special devices or change of equipment, or, in other words, the fact that carbureters as at present designed are capable of handling fuels of varying densities without any radical alteration. It goes without saying that in a specially designed motor, having much higher compression and a longer stroke, alcohol would make a far better showing.

GETTING UNDER WAY FOR THE DAY'S WORK.

AMERICAN DETACHABLE TIRES AND REMOVABLE RIMS

By C. B. HAYWARD.

THAT the standard type of clincher tire on the standard type of rim has been able to hold its own despite the great amount of attention paid to mechanical forms of fastening and the number of devices of this nature that have made their appearance on the market within the past few years, may be taken

finally developed with a stiff retaining bead, is but one of the numerous instances in which practice utterly flouts theory, for it did not appear possible that the force of inflation alone could ever suffice to prevent the tire being torn from the rim of a heavy car at high speeds, and this is what led makers to undertake the development of a mechanical type of fastening at an early day. Tire lugs were recognized as necessary to give that factor of safety required to avoid creeping with its attendant evil of stripped valves, but it was also realized that at best they were but a makeshift—without them

SECTION VIEW OF FISK RIM.

the clincher was not safe and with them it did not represent a convenient or readily detached form of fastening, which is doubtless accountable for the fact that the lug nor anything akin to it has been perpetuated in any of the forms of mechanical fastening

that have been developed in the interim. The problem is complicated at the outset by reason of the varying requirements to be complied with, in that the fastening must grip the tire like grim death, and yet permit it to leave the rim without the necessity of going through an operation similar to that of breaking into a safe deposit vault. It has been approached in a variety of ways, but with all their seeming differences it will be found

GENERAL VIEW OF FISK RIM.

upon investigation that experimenters have met, with few exceptions, upon a common ground where basic principles are concerned, which probably explains the general measure of success that has attended their efforts as represented by the devices now on the market. Daily experience alone will develop the type most perfect in its details.

Progress Revealed.

As in many other things, while there were tire users galore who consigned the clincher tire and all its drawbacks to perdition every time they had occasion to remove or replace one on their cars, making vows in the meantime that they would be the first to adopt a better fastening if some genius would only condescend to evolve it, the manufacturer who did so encountered the inevitable and almost immovable inertia

PENNSYLVANIA DISMOUNTABLE RIM.

AJAX TOURING RIM.

AJAX RACING RIM.

to mean that none of the inventions in question have proved to be the success anticipated for them by their sponsors, or that, being a success, they have not yet reached a stage where their merits have been brought home to a sufficient number of tire users to make their adoption general. The autoist who has not given the subject more than passing attention is apt to incline to the former view, while between this hasty assumption of failure, arising chiefly from the conservatism of the tire user at large, and the opinion of the mechanically fastened enthusiast which admits of the existence of no other form, there is the large army of every-day tire users who have no preconceived opinions one way or the other. It is in the ranks of the latter that the maker seeks for converts, and any man who has ever struggled with a refractory clincher in the large sizes now in vogue is more than willing "to be shown."

Experiments Date Back to Early Days.

To those who have followed the evolution of the pneumatic tire, as applied to the featherweight bicycle, through the various

CLIP WHICH HOLDS ENDS OF AJAX RIM TOGETHER.

stages it has been compelled to pass in order to make it capable of supporting many times its former total load and at speeds hitherto undreamed of, it is unnecessary to recall the fact that the mechanically fastened tire is not something of recent origin; comparatively speaking, of course, as the automobile tire of any sort is but of infantile age. The success of the clincher tire as

that waits "to see the other fellow buy it" before investing, when it came to the matter of marketing their devices. Anyone who had given the subject a thought, whether mechanically inclined or not, could hardly have failed to realize that some positive method of fastening was bound to come sooner or later, just as surely as the automobile is certain to displace other forms of transportation in time. But neither his knowledge of that fact nor his desire to see it materialized were sufficient to cause him

SECTIONAL VIEW MARSH RIM.

to become an advocate to the extent of setting an example to his fellow-autoists by adopting any of the devices on the market for his own car. This is the situation that has confronted the manufacturers all along; there was so much dead weight to be moved that the progress toward popular favor was necessarily tedious, with the result of

one year's work not greatly in advance of what had preceded it. Then came the advent of the simon-pure removable rim for racing purposes, and with a start the automobile-using public woke up gasping to the fact that the simple device which had accomplished such marvelous results in the way of time saving, was nothing very different from that they had had before them at home for some time previous.

Widespread interest in mechanical forms of fastening really dates from that occasion, such is the curious turn that things insignificant in themselves will sometimes give the trend of general opinion. With one or two exceptions the entire American tire industry was to be found grouped about the gallery of the Coliseum so that a better opportunity to see and compare the combined results of efforts along this line could hardly have been desired.

Dismountable Rims Not Numerous.

Where what is known as the true dismountable type of rim is concerned, this is not much in evidence, the makers of the

Ajax and Fisk and of the Pennsylvania tires being the only ones to show devices of this kind. The remainder are in the class of detachable or mechanically fastened tires and the progress the latter have made is well evidenced by the fact that there is not a maker of tires to-day whose showing does not include something of this kind, whether of original invention or made under license from the patentees. The Ajax removable rim is only made in what is termed

GOODRICH TIRE AND RIM.

a racing type, designed for that extremely exacting service.

This differs considerably from what is termed the Ajax "tourist rim," which is really a detachable tire. The wooden felly of the road wheel carries a fixed steel rim, permanently bolted to it. To retain the removable rim, the inner edge of this fixed rim is raised and three grooves are cut across its surface. The tire is mounted on a separate steel rim, inflated and held in position in the usual clincher manner. The inner face of this steel rim carries three metal projections or wedges, corresponding to the grooves on the fixed rim. Special safety bolts, counter-sunk, are employed, and, as the tire never needs to be inflated on the wheel, a similar type of valve can be used. The tire mounted and inflated in advance on the detachable rim, the whole is slipped on the wheel, the projecting wedges coinciding with the grooves, a catch is released, the expanding band springs open and the tire is ready for running. Creeping is prevented by the grooves and wedges, and any possibility of flying off sideways is prevented by the expanded band. The entire circumference of the wheel being a bearing surface, there is not the danger of stretching common to some types of rim. An Ajax racing rim has been removed and replaced by a new one in 14 3-5 seconds.

The tourist rim consists of a main rim or base member permanently fitted to the wheel, carrying on one side an ordinary clincher or bead. The opposite or outer edge of the base member is provided with a slot or groove around its entire periphery from three-eighths to five-eighths inch deep, according to the size of wheel. In this groove is placed a split metal locking ring which is contracted and expanded by means of projecting tips. On the same edge is a flat steel band turned up on the fixed rim one-eighth of an inch. This turned edge acts as a check against which the removable bead or clincher fits. The outer removable clincher is also fitted with a groove on its inner face, which the locking ring in its expanded position entirely fills, holding the rim rigidly on the wheel. To take out an inner tube is an exceedingly simple matter. A small metal wedge between the two ends of the expanded band is withdrawn and the two tips brought together and held in a contracted position by the clip shown in engraving. There being now nothing to hold it, the outer clincher drops off, and the shoe and inner tube can be slid off the fixed rim. The operation is so simple and requires so little muscular effort that a child could perform it. No nuts, bolts, or other tightening mechanism are employed, nor is any special tool necessary for operation. Lugs or bolts may be used and the ordinary type of valve is employed.

In the case of the Fisk, a simple but highly effective principle that has hitherto not been taken advantage of in this connection has been employed. The inflated tire is held on the dismountable rim with the familiar Fisk type of mechanical fastening, which is one of the oldest of its kind on the market. The center

MIDGLEY TURNBUCKLE.

CROSS SECTION OF THE DUNLOP.

UNIVERSAL RING OF THE MIDGLEY.

of the wheel is held in position by the universal ring of the Midgley. This ring is contracted and expanded by means of projecting tips. On the same edge is a flat steel band turned up on the fixed rim one-eighth of an inch. This turned edge acts as a check against which the removable bead or clincher fits. The outer removable clincher is also fitted with a groove on its inner face, which the locking ring in its expanded position entirely fills, holding the rim rigidly on the wheel.

To take out an inner tube is an exceedingly simple matter. A small metal wedge between the two ends of the expanded band is withdrawn and the two tips brought together and held in a contracted position by the clip shown in engraving. There being now nothing to hold it, the outer clincher drops off, and the shoe and inner tube can be slid off the fixed rim. The operation is so simple and requires so little muscular effort that a child could perform it. No nuts, bolts, or other tightening mechanism are employed, nor is any special tool necessary for operation. Lugs or bolts may be used and the ordinary type of valve is employed.

of this dismantable rim has a raised section with sloping sides, one of which engages a corresponding raised edge on the permanent metal rim bolted to the felly. When the rim with its tire is put in place this holds it at the inner side. The felly of the wheel and a split ring with a beveled face at an angle of about 45 degrees corresponding to a similar face on the permanent rim, are pierced at regular intervals with six bolts, fastened so as not to turn or shake loose. When the nuts on the latter are tightened, the ring expands, the two faces sliding on one another, causing it to rise vertically, thus firmly gripping the rim between two substantial metal rings. As it is only necessary to give the nuts a few turns to loosen them, and they never have to be removed, the operation is one requiring but a very short time to complete. In addition to marketing this new type of rim the regulation Fisk detachable type will be continued.

GOODYEAR DETACHABLE TIRE.

The Pennsylvania is the only other true dismantable rim produced in this country, and presents the extreme of simplicity. It is based on a radically different principle than either of the other two just described. The permanent rim attached to the felly of the wheel is made with special recesses or wide slots corresponding to detents or raised portions on the removable rim. The countersunk portions of the permanent rim are tapered in a direction contrary to that in which the wheel runs, so that the strain created by the latter when under way only tends to force the rim and tire on more tightly. In order to prevent lateral play, which might cause the rim to fly off the wheel sidewise, the sides of the detents are engaged by the sides of the recesses, and a further precaution is added in the shape of two substantial set-screws, which constitute the only part of the device requiring the use of a tool of any kind. The rim carrying the already inflated tire is slid on, given a turn backward for an inch or so, to cause the detents to engage, and the two set-screws tightened, completing the operation, the latter being reversed to remove it, and both being possible of accomplishment by an unskilled driver in less than two minutes, including the preliminary work in the shape of raising the car on the jack.

Large Showing of Detachable Tires.

It is to the field of mechanically fastened tires that the American maker has given up a very large portion of his time, and the result is evident in the number of this type of devices now to be found on the market. Every one of these inventions has been the result of extended investigation and experimenting on the part of those responsible for them, and as practically all of them appeared within a very short time of one another, it would be difficult to treat them chronologically. With the exception of the Fisk, which, as already mentioned, uses transverse bolts and was one of the

SECTION OF GOODYEAR SHOWING VALVE FASTENING.

first to make its appearance, there is considerable unanimity of opinion with regard to the basic principle of nearly all these devices, this consisting of the use of one or more loose rings. It is in the method of attaching the latter and making it fast that the greatest difference is to be found.

In the Marsh rim, for example, which is put on the market by the Diamond tire interests, this takes the form of a small key-piece. As shown by the section illustrating it, the rim is provided with a threaded extension passing through a hole in the key-piece when the latter is placed in the opening between the ends of the split ring. A nut is tightened on this threaded end and provides against any possibility of the ring jumping out of its channel or being thrown off sidewise, though experience with this rim has shown that it can be run with perfect safety, even though this extra precaution be not taken. As has come to be the case with every maker of detachable tires during the past year or two, the necessity of making the rim so that it could be used with every form of standard tire was apparent at the outset, so that the Marsh rim was given this characteristic at the start. With interchangeable flange rings, the Marsh rim adapts itself to the Dunlop type of tires, or by the use of stay-bolts it makes Diamond regulation clincher tires an entirely convenient and safe equipment.

In the Goodrich quick detachable tire, the construction of the latter is exactly the same as the standard clincher tires made by this firm, and as the dimensions of the rim are standard, the

FIRESTONE, CABLE TYPE.

FIRESTONE, CLINCHER TYPE.

latter will readily accommodate itself to any make of clincher tire manufactured under the G & J patents. The removable ring in this case is provided at its ends with two substantial hooks of almost square section, and a specially shaped slot in the permanent rim on the wheel itself. This is somewhat on the form of an exaggerated letter Z with a long and a short horizontal bar and without any independent connecting line between the two, its outline being well illustrated by the accompanying illustration of the rim and complete wheel. The two hooks of the removable ring are dropped through the long opening of the slot, which is innermost, and then forced, one after the other outward and into the shorter one, which they completely fill. A handy tool is provided for this purpose. The construction is such that when in place the inflation of the tire contributes very largely to its holding power. A dowel pin insures the placing of the ring in the proper place, while the dust cap provided for the valve also acts as a retainer, with the result that the tire does not creep and cannot blow off the rim whether inflated or otherwise.

The familiar principle of the turnbuckle has been taken advantage of in the case of the Midgely rims used in connection with the Hartford and Dunlop tires, as well as of those of other makers manufacturing it under license from the patentees, as is the case with Morgan & Wright. The greatest drawback of the turnbuckle in the form in which it is best known is the length of time required to adjust it. This has been overcome by the addition of a device which is at once a multiplying gear and lock. It is constructed on the familiar principle of the worm and spiral, and with the aid of a small crank, which is the only tool necessary, the turnbuckle may be drawn up or loosened in a fraction of the time necessary with the ordinary type. The crank is provided with a square shank fitting a similar hole in the center of the worm, and as the latter and the gear with which it meshes are so cut as to form an irreversible unit, no amount of strain on the

split ring causes this gear to turn the worm when running. This precludes the necessity of any other form of locking devices, as the ring is bound at whatever point the turnbuckle is tightened to. The beads of the tire itself are held between a floating ring on which the tube rests, and the retaining rings.

The Goodyear universal rim is the oldest rim of its kind on the market—that is, one having removable endless flanges. As its name indicates, it is designed to take either the Goodyear detachable tire or any standard type of the G & J clincher. It consists of a rolled steel base

CROSS SECTION REPUBLIC TIRE.

permanently attached to the wheel, two flanges or hoops adapted to slide on and off the base easily and a split locking ring. The last named drops into the usual channel in the base and prevents the flanges from being pushed off when the tire is inflated. A spreader plate carrying a thumb nut goes over the valve and, when drawn down, presses the flange against the split portion of the locking ring, so that it cannot be lifted out or removed from the channel by any strain regardless of the direction from which it is exerted nor its severity. No special tools of any kind are required and the operation of removing or replacing a tire is very speedily accomplished.

In the case of the Firestone, the rim is fitted either with flanges for a cable bead tire casing or flanges for the regulation clincher type. In the former case the rim will take the Firestone mechanically fastened tire and in the latter any standard form of clincher. Both the casings and rims are interchangeable with other standard quick detachable rims and casings. The flange

and tire are held in place by a simple and ingenious safety locking ring slipping into a channel, creeping being prevented by a spreader attached to the valve stem, a wrench being the only tool necessary to remove or replace the tire. The removal of the locking ring permits the flange and tire to be slipped off the rim. The illustrations show the difference between the cable and clincher bead types.

REPUBLIC WHEEL AND RING.

Particular attention has been paid to the matter of excluding dirt and water as well as confining the air to the interior of the tire proper in the evolution of the quick detachable type put on the market by the makers of the Republic tires. So far as the tire itself is concerned, this is somewhat on the lines of a combination of the cable and clincher types, a special feature being found in the addition of a soft rubber strip along both inner edges of the beads, thus effectively protecting the inner tube, the perfect joining of the base preventing pinching of the tube—a most prolific source of so-called punctures. A locking ring secured in place by a retaining nut at the base of the valve constitutes the form of fastening employed, in addition to a keypiece placed opposite the valve and completing the flange ring, which forces the locking ring snugly down into the channel and onto the wheel.

Where other prominent firms are concerned, those who have not brought out special devices of their own, manufacture some of those already on the market under license from the patentees. For instance, the makers of the G & J tires and Morgan & Wright also make the Dunlop and clincher tires for use on the Midgely universal rims, so that every prominent maker of pneumatic tires in the country is making a device of this kind, whether of his own invention or not.

MECHANICAL TIRE INFLATOR PERFECTED.

For three years the experts of the Michelin tire factory at Clermont-Ferrand have been studying the problem of mechanical tire inflation. The result of their labors has just been given to the public in the shape of a machine of very ingenious construction, which, with the engine as motive power, will inflate the largest tire in five minutes. At present the apparatus can only be used for four-cylinder engines, but there is no reason why it

MICHELIN MECHANICAL PNEUMATIC TIRE INFLATOR.

should not be modified for use on a two-cylinder, or even a single-cylinder engine. The Michelin apparatus consists of a compact little pump no larger than the two fists, which may be mounted in any convenient position and connected up to two of the cylinders by a couple of flexible pipes. Valves and taps are placed on these cylinders so as to cut off the supply of gas and allow only pure air to enter, while the other two cylinders are set working. Thus two cylinders are working under normal conditions, and two are compressing air and sending it to the pump. But the pressure of air from the cylinders is not sufficient to inflate a modern tire, and for this reason the pump has to be employed to increase the pressure. The manner of doing this is simple but clever. The air supply to the pump is divided into two parts; one acts on the large end of a piston in the pump, and the small end of this piston compresses the second supply of air to the required degree. The relative areas of the two ends of the piston being as 5 to 1, the air entering the pump at 2 kilograms pressure leaves it at 10 kilograms, this being a sufficient pressure to insure rapid and satisfactory inflation of the tire. From the air outlet shown on the right-hand side of pump a pipe leads up to a terminal on the dashboard, and from this point a connection is made to the tire valve by a rubber piping in the ordinary manner. The apparatus is extremely robust; when once fitted it needs no attention or lubrication, and does not necessitate the use of chain, gears, or belt.

A new bearing metal, composed to a large extent of cadmium and antimony, is being developed in England. The cost of the new alloy, however, is said to be practically prohibitive for general purposes, owing to price of cadmium, its principal component, ranging in the neighborhood of one dollar per pound.

THE HORSE AND THE AUTOMOBILE

By VICTOR LOUGHEED.

ONE of the least understood of the industrial and sociological phases of the automobile development is the relationship borne by the new conveyance to the field of the horse. So far—to the satisfaction of the opponents and the confusion of the advocates of the motor vehicle—it is the evidence of a casual view of the situation that the quantities of automobiles placed upon the market have made no very perceptible inroads upon the mode of transportation they are destined to supplant.

Horses to-day, in most localities of the United States, sell as numerous and for as high prices as ever, while in some localities they bring even more; in every community in the country, for each automobile enthusiast found spreading the propaganda of the new conveyance there are to be found a thousand hard-headed, sensible people, perfectly willing to be "shown," but who nevertheless are skeptical in regard to both the present importance and the future prospects of the automobile; and there are several manufacturers of horse vehicles whose factories boast an *annual* output numerically equaling the total output of automobiles during the history of the industry in this country!

All of these statements are statements of fact, and as facts are to be reckoned with if the automobile is to achieve the goal for which it is clearly headed—the practical extinction of the horse. Consequently, a statistical study of the situation is the only possible means of reaching a really well-founded opinion as to what are to be the lines along which the industry is most likely to expand. Something of this sort was presented by the writer, in an article captioned, "The Field for the Automobile," which appeared recently in *THE AUTOMOBILE*—in the issue of November 1, 1906. The figures therein given were taken directly from the Reports of the Eleventh Census—the census figures fortunately being very clear and complete on this interesting subject.

Two-thirds of Horse-drawn Vehicles Made for Pleasure.

By these census reports, it was shown that the annual production of horse vehicles of all kinds in the United States during 1890 was 1,369,254, and in 1900, 1,603,371. Since these decennial reports, supplementary reports have been issued, indicating an annual output now of something slightly over 1,700,000. Incidentally, there is disclosed the decidedly significant fact that fully two-thirds of all the horse vehicles made are distinctively pleasure vehicles, while three-quarters of these—one-half of the total—are specifically *two-passenger* pleasure vehicles. Also, the heavy commercial vehicle, which is accredited by nine men out of ten in the automobile industry with some almost inexpressibly great future, certainly can invoke no horse-vehicle parallel to indicate a grain of reason in this awestruck regard for its future.

Of "*drays and trucks*," the 1900 census reports state, there were then made 7,417 annually—a little more than one one-thousandth of the complete output. Of "*furniture vans and caravans*," there were 1,725; of "*coal wagons and carts*," 3,155; of "*dump wagons and carts*," 4,098; of "*ice wagons*," 1,144; of "*log and ore wagons*," 4,282; of "*public conveyances*," 2,316; of "*trade wagons*," 11,788; of "*street sweepers, sprinklers, etc.*," 491; and of "*government and municipal wagons*," 1,108; besides perhaps another thousand in miscellaneous classes. The total of these is 31,107—.019 per cent. of the total. "*Farm wagons and carts*," to the number of 405,513, and "*business wagons*," to the extent of 125,726—the two totalling nearly one-third of the total output—at first sight make a more respectable showing, until analysis of their subclasses discover that nine-tenths of these are the lighter vehicles, not likely to be competed with from automobile standpoints except by the use of special bodies on accepted pleasure types of chassis.

Of course, nothing in the foregoing denies a very great field for the commercial automobile, but this is true, not because of its comparative importance, but because a demand for even 50,000 or 60,000 commercial vehicles a year is an ample basis upon which to found a great and important industry

But, in the writer's opinion at any rate—and all the evidence to be had bolsters up this opinion—the tremendous field for the road vehicle of the future is the truly tremendous field filled by the road vehicle of the present.

And the average road vehicle of the present is not a multi-millionaire's "locomotive of the highroad," nor even a \$500 run-about or a \$1,000 touring car; it is a \$95 two-passenger buggy, drawn by a horse worth perhaps \$100, and equipped with accessories, harness, etc., probably totalling not over \$55 more. Consequently, the complete road unit most in demand to-day is that for which the purchaser is willing and able to pay, and is in the habit of paying, about \$250.

Facts That Are Interesting and Very Significant.

With an annual production of 1,700,000 horse vehicles, of which fully 1,000,000 are pleasure vehicles, is it not reasonable to presume that at least as many as 40,000 of these—only 4 per cent.—are of the high-grade, expensive, luxurious types, naturally associated with silver-mounted harness, footmen and coachmen, flunkies, and other of the money-absorbing appurtenances of wealth? And is it not equally safe to assume that these vehicles, fully equipped for the road—with horses and with harness—will cost on an average fully \$1,500?

Yet, it is an absolute fact that the automobile industry in this country, rapidly as it has developed, has only now reached an annual production of about 40,000 vehicles of all classes, retailing for an average of about \$1,500 each—in condition to run upon the road.

What more natural, then, that in these days of its sturdy infancy, the automobile should compete first with that phase of horse use wherewith competition is the easiest, requirements the simplest, money the freest, prices the highest, and profits the greatest? What more natural than that the hazards of catering to a low-price quantity demand, involving the risks of heavy investments for quantity production and the assurance of small profits, should be temporarily neglected in the rush to till the field of greater immediate promise?

Viewed in this way, the situation is perfectly logical and readily understandable. It obviously is a necessary condition in the economic evolution of an engineering industry. Through catering to the demand that has possessed the "price," and therefore could afford to experiment, the experimental period has been passed with a painlessness and general satisfaction that could not have developed in any other circumstances.

To-day, as the result, any concern with average good designers and large manufacturing and selling resources, could conservatively embark on the construction of 100,000, or even 500,000 low-priced automobiles, all alike, with every assurance that all would sell quickly and give the buyers their full money's worth of service for years to come.

The efficiencies of quantity production, applied in connection with the best that is known of simple and reliable designs, would insure a consistent quality and a price, which alone would constitute most of the selling argument necessary, thus saving much of the tax on the marketing.

The Horse Is Distinctively Losing Ground.

In the meantime, the horse reigns only in the fields in which his supremacy has not been disputed. This may be startling, but it certainly is true. Let any one consider for a moment, and it must be admitted that in those of his activities that involve catering to luxury and the long purse he is distinctly losing ground. He has lost ground. He is no longer used by the ultra-fashionable and the pleasure-loving to the extent that he once was. The riding and driving clubs all over the country are losing membership, and even closing their clubhouse doors, and livery stables are losing money or being transformed into garages.

The remaining stronghold of the horse is guarded solely by low prices.

The horse-vehicle production for 1906 was only 1,700,000, which indicates that the 1,877,517 required by 1910, if the past rate of growth is to be maintained, is going to fall about 140,000 short. Significant fact!

This is almost exactly the number of automobiles likely to be in use at that time, if present-day figures extend as the logic of the statistician argues they will.

In other words, for every automobile placed in commission in one place, a horse vehicle has gone out of commission there or in some other place. And the law continues to apply, inexorably. The horse has made and is making no stand whatever against the rising tide of mechanical propulsion. He persists in use, not because of his merits nor because of the difficulty of winning the victory over him, but because it takes time to organize to assail him. It is altogether a matter of time, not of difficulty. His strength is a sheer numerical strength.

The horse simply has not been assailed in his most numerous field of usefulness by the automobile, and his most numerous field of usefulness is a matter of something like a million a year of two-passenger, \$250 conveyances!

The average horse user, in other words, is of the people. In

proportion as he is numerous, he is individually weak financially. The automobile user, on the other hand, though less numerous, has been of a higher financial strata. Wisely, manufacturers have catered to him. But now the industry has developed and the situation is changing. Perhaps the price of \$250 need not even include a full running equipment. The cost of tires, for instance, might be left out of consideration altogether, with the advantage of eliminating the present unsatisfactory practice of placing cheap tires, of too-small sizes, on cheap cars. Tires being a considerable running expense, there is no more real reason for including them in the list price of an exceedingly low-priced car than there could be for selling the same car with the gasoline and oil tanks filled, or a horse with enough shoes and hay to enable him to travel 10,000 miles—the approximate life of a tire.

It is to the credit of, rather than a reflection upon the present status of the automobile industry that the day of the low-priced car is dawning. When the masses, as well as the classes, can possess automobiles, the number of sales will more than compensate for any possible reduction in the profits upon sales. And, as has been said before, will not the low-priced car, by its widespread use alone, do more in months for the good-roads and fair-legislation propogandas than has been done in years by all the other interests enlisted behind them?

ADVANCE OF THE MOTOR 'BUS IN THE GREAT CITIES

AS copy providers for the British daily press the London automobile 'buses are unique. Columns upon columns have been written on their side slipping proclivities, their noise, their smoky exhausts, dangers of fire, damage to property through vibration, etc. Despite all the criticism, the 'buses have continued to grow in numbers at the expense of the horse-drawn vehicle. If proof were needed of their success it is to be had in the reports of the London transportation companies. Even the Electric Underground Railway Company, with the best equipped plant in the metropolis, quick trains and low fares, has to announce a large diminution in its takings as the result of the competition of auto 'buses. The majority of the London 'buses are gasoline driven. A small number are British-built steamers, and the latest addition

is the electric 'bus shown in our illustration. A uniform type of body has been adopted, as shown in the engraving, with transverse seats on the top. More than half the gasoline 'buses are of foreign origin, De Dion-Bouton, of Paris, having supplied a large number, other big furnishers being Mors and Lacoste & Batmann. Germany has succeeded in capturing a large amount of the London 'bus trade. One of the De Dion 'buses, similar in every respect to the London article, is daily running on Fifth avenue, New York, as an experiment. All Paris 'buses, about fifty in number, are of the Eugène Brillée type, driven by 40-horsepower gasoline motors. The Serpollet-Darracq combination is seeking to take over the entire Paris 'bus service when the present company's lease expires, and provide a complete service of steam vehicles.

ONE OF THE FEW ELECTRIC 'BUSES NOW BEING OPERATED IN THE FASHIONABLE WEST END OF LONDON.

LETTERS INTERESTING AND INSTRUCTIVE

A Novel Automobile Wheel.

Editor THE AUTOMOBILE:

[570.]—I would like to ask a question in regard to the wheels in present use on all automobiles, that is, whether the standard artillery wheel is giving perfect satisfaction at present, or whether it could be improved on or not. My reason for asking is that I have a model wheel, which I am having patented, and which I think is an improvement over other wheels, as it is a device whereby we get a complete staggered-spoke wheel and employ no bolts whatever, while we can use from ten to thirty spokes in each wheel if desired. This, I think, would make a much more substantial wheel than the regular artillery. And another feature is that it will not require much machine work in its construction—only to cut a thread on both sides of the hub, also inside of a retaining ring that screws to the hub to hold the spokes in place. When it is complete, it makes a decidedly rigid and stout wheel. In case of an accident, one can remove all spokes from one side and replace them in a very short time without interfering with the form and shape of the wheel, and without taking it all apart. Now I would like to have your opinion of such a wheel, and whether you think there would be a market for same, before I go ahead with it. If you can enlighten me on the subject I would be obliged.

WM. VAN ETTEEN.

Richmond, Va.

Without seeing the actual wheel itself, it is difficult to say with certainty whether or not you have something capable of being marketed at a profit. Even then, so much depends upon the strength of the backing you have, and upon the business ability that may be at your command, that we could not hope to furnish an offhand opinion likely to be worth anything to you. There is no doubt but what many now popular automobile wheels might be readily supplanted by something altogether superior, and it is a fact that a lot of people believe the staggered-spoke wheel is better than the artillery wheel. It is usually more complicated, however, and harder to repair, though it has been more used on horse vehicles than the artillery wheel. Personally, we do not particularly fancy the great number of spokes you suggest, though this is only a detail, undoubtedly capable of modification. In the small sizes commonly used for automobile wheels, the unsupported portions of the spoke will hardly average more than seven inches—certainly short enough to stand up regardless of the construction employed. We would suggest your reading up on wheel patents before going ahead, since there has been an immense number of devices brought out along the line you mention, and there might be something that would conflict.

A Hasty Conclusion.

Editor THE AUTOMOBILE:

[571.]—In your issue of January 24, on the pages devoted to correspondents' letters, you take Mr. Clarence Jones, Columbia, S. C., to task for his statements in regard to current consumption in (letters 543). You state that he neglects to consider that an engine running at 1,500 revolutions to the minute makes contact twice as often as one running at 750. This is certainly true, but it is also just as certainly true that each contact is exactly half as long, therefore the total time of contact is the same in either case. In one case, at 750 revolutions, we have a certain number of contacts of a certain duration every second, and at 1,500 we have twice the number of contacts of just half the duration, so there would be the same battery consumption in either case. It seems to me these considerations would convince any one that battery consumption is absolutely independent of motor speed, except that it might be influenced by the lag of coils and timer.

THOMAS C. FORBES.

Los Angeles, Cal.

We think that you rather miss the point of our contention in assuming that battery consumption is determined solely or chiefly by the duration of contact. You are correct, of course, in what you point out—that at double the speed of rotation the duration of contact is halved—but it seems to be generally believed that there is a surge of the current upon the contact being made which has much more to do with battery consumption than the mere duration, which is very short, even at the longest.

An Unusual Type of Accident.

Editor THE AUTOMOBILE:

[572.]—I have just read an account of an automobile accident in which a man was killed by the explosion of a flywheel, due to its being run at too high a speed. Will you please tell me exactly what can cause such an accident, whether it is one that can occur to any automobile if the engine is run too fast, or whether it is due to some defect in the wheel, such as probably would not exist in some other wheel on the same make of car. Also, is it the centrifugal force or some other effect that causes the breakage? I understand that the flywheel of any large stationary engine is almost certain to break if the engine is speeded way above its normal speed. Is this true of automobile engines also, and, if not, why not?

GEORGE ISAACS.

Durham, N. C.

The laws of mechanics are the same in the bottom of the sea or on the top of a mountain, and what is true of the flywheel of a stationary engine may also be true of the flywheel of an automobile. The flywheel of any machine must be designed to run at a certain maximum speed—either the maximum at which it is possible for the machine to run or a maximum determined by some safety-controlling device. This maximum involves a certain peripheral velocity, which, with a given weight involved, results in a given centrifugal force. Strength sufficient to resist this force must be provided in the design, and if it is not provided—because of faulty design, flaws or imperfections in the material, or a wrong conception of the maximum speed—the flywheel is highly dangerous, being likely to break with the result that fragments will fly around like projectiles. Another factor that sometimes has a part in flywheel breakage is gyroscopic action, coming into play when the bearings are loose or the center of gravity is not at the center of rotation. Of course, this effect is more likely to break crankshafts than flywheels, unless the latter are unduly weak in the spokes or web.

Causes for the Heating of Tires.

Editor THE AUTOMOBILE:

[573.]—Can you tell me whether the heating of automobile tires and consequent separation of the plies of the outer shoe and destruction of the inner tube is caused by the frictional contact of the tire with ground, or the internal friction of the air confined in the tube; or do both contribute as causes of the heating and in what proportion?

It is claimed that the larger portion of the heat is generated by the velocity with which the air is forced round the inner tube, the air being circulated in the inner tube in a direction opposite to that in which the wheel is revolving, by the contact of the tread of the tire with the ground. The weight of the car flattens the tire from a round to an oblong or elliptical form and continually forces or pumps the air in the tube in the direction opposite to that of the wheel's travel, the continual flattening of the tire when in motion also causing a "pounding" of the air in the inner tube at a point where the shape changes or flattens when in contact with the ground, superheating and expanding the air.

As an illustration, a 34-inch tire on a car running at the rate of 40 miles an hour would make approximately 380 revolutions per minute. The circumference of the tire being 106.76 inches would make the tire rim travel 3,380.75 feet per minute and the air in the tube circulating in the opposite direction would have a frictional travel of 6,761.50 feet per minute approximately, or about 1¼ miles per minute, and the propulsion of the air through the inner tube at this tremendous speed would heat and expand it to such a degree that the tube would burst. I claim that 75 per cent. of what are called punctures are really ruptures of the tire caused by the expansion of the air in the inner tube. I would be very glad to hear from anyone who has given any thought or study to this phase of the heating of the inner tube of automobile tires.

Buffalo, N. Y.

JAMES F. PRESTON.

While we have been unable to find any definite data on the subject, we think it is evident that the disintegration of a pneumatic tire is due both to the friction of the shoe against the road as well as the friction of the tube and inside of the shoe, and that by far the greater part of it arises from the constant bending of the outer shoe at its sides. In fact, the latter would

appear to be almost wholly responsible for the separation of the various plies of the shoe which will usually be found to start at the point which is subjected to the greatest amount of bending. The rapidity with which a tire disintegrates depends upon the care given it more than anything else, all other things being equal. The destructiveness of this bending is the chief reason for the stress laid upon proper inflation by the tire maker.

Assuming your figures to be correct in the instance cited, the conclusion that it is impossible to run a car with pneumatic tires at a greater speed than 40 miles per hour would appear to be inevitable. As you are probably aware, speeds in excess of 100 miles per hour have been attained, and though the tires have become very hot they have neither melted nor suddenly disintegrated in any other way by reason of it. The error in your calculations would seem to arise from your assumption that the air only travels in the inner tube in one direction as the result of expansion, and that direction must necessarily be the reverse of that in which the wheel is turning. If we assume, for instance, that, with the revolution of the wheel, as each point comes round and makes contact with the ground, its meeting is similar to a blow, of which the expansion is the result, it will be evident that the air must travel in opposite directions away from the point of contact. Owing to the forward travel of the wheel and the manner in which it meets obstructions, it is probable that this is not equally divided vertically, but that a larger fraction of it is toward the rear from the point of meeting, and, consequently, in the same direction as the wheel is traveling. Expansion is always along the line of least resistance, and as there is nothing to prevent the air in the tire traveling one way round it to the exclusion of the other, it is evident that it takes both ways round, and, meeting half round, the force of each stream is counteracted by the other, so that there is no constant stream of air circling the tire at a tremendous velocity such as you have figured out. Take a piece of ordinary garden hose long enough to make the equivalent of a tire, and bend it in circular form; hold it upright and strike it a blow with a mallet at the point it touches the ground, and the conditions under which a tire travels will, in a measure, be simulated. If there be any means of measuring the force of the air issuing from each open end of the hose as a result of the blow it will undoubtedly be found to be approximately equal in each case. There is little doubt but that a very large proportion of the alleged punctures are "ruptures" of the inner tube, but if the truth were told they would be called "pinches" due to carelessness in putting the tire on. If there are any of our readers who have had any experience of the nature in question, and can amplify the foregoing, we should be pleased to hear from them.

The Balancing of Engines.

Editor THE AUTOMOBILE:

[574.]—I have never fully understood the balancing of different types of engines, and would very much appreciate an explanation in your columns "Letters Interesting and Instructive." I can understand that a two-cylinder, opposed motor is in balance. I am told that a vertical two-cylinder motor with cranks 180° apart is in balance as to its reciprocating parts, but that there is some sort of accelerating force not compensated for. This is not clear to me. Does a four-cylinder vertical engine overcome the difficulty, if there is one? What forces in a vertical, single-cylinder engine have to be counterweighted? Does the balancing hold good for all speeds? If not, why not?

New York City.

There are a good many factors to consider in the balancing of motors, by which it is sought to avoid undue vibration. The most obvious factors to be considered are, of course, the balancing of impulses and of moving parts. All that can be done with respect to the former is to cause them to occur at definite and invariable intervals during the crankshaft rotation. The balancing of moving parts is less simple. A horizontal-opposed motor is in very good mechanical balance because the pistons approach each other and recede at rates that are at all times the same for both pistons.

With a vertical motor the movement of one piston down does not balance that of another piston up, because of the angularity of the connecting rods. Because of this angularity, when the throws on the crankshaft are horizontal, both pistons are materially below the center of the stroke, as you will realize if you conceive one of the pistons held in place and the bottom of its connecting rod released from the crankpin and swung into a vertical position, in which position it will reach materially below the center of the crank circle. And, since in turning from the horizontal position to a vertical position of the crank throws, the rising piston must travel more than half a stroke and the falling piston less than half a stroke, it follows that they move at differing speeds, and thus do not exactly balance each other. Another condition that arises with a vertical, multicylinder engine is due to the presence of a rising piston at one end of the range of cylinders with a falling piston at the other, this action tending to produce a rocking motion from end to end of the motor. A counterweight on a single-cylinder motor is designed to balance the weight of the connecting rod opposite it, besides partially balancing the piston. Such balancing does not hold good for all speeds because the balancing effect varies at different points in the revolution, with the result that the motor cannot run evenly, besides which the variations in torque are not compensated for.

A Case of Leaky Valves and Defective Coil.

Editor THE AUTOMOBILE:

[575.]—I have read with considerable interest communication 542 which appeared recently in "The Automobile," under the head of "Letters Interesting and Instructive." In view of the fact that I have experienced very similar difficulties with my four-cylinder 22-horsepower European automobile, I might add, however, that one of the difficulties I have experienced is the failure of the engine to occasionally respond to the throttle when it is opened, whereas, one would fully expect the engine to fairly roar when the throttle was opened wide, particularly when running on the intermediate gear.

Quite recently I noticed a coating of oil or fluid on the top of the last cylinder and on close investigation I found that this oil was oozing through the cap which screws into the head of the cylinder, but whether or not this defect would have the same effect as the leaky valve described by you, I am unable to say. Can you give me any information on this point? I would also like your explanation of the following:

As a result of my search for these difficulties, I quite recently learned of a short circuit in my coil box. The ignition on my car is by means of a magneto and a set of accumulators, and in the coil there is provision for a short circuit between a lever and one of the terminals for the purpose of preventing the coil burning out. It is at this particular point that the short circuit occurs.

Toronto, Ont.

OSLER WADE.

Without more definite particulars or a personal inspection of the car, it seems difficult to ascribe the condition such as outlined by our correspondent in letter 542 to be due to anything but poorly fitting valves, and if the symptoms of your trouble are identical with those there outlined, we should recommend the same remedy. Occasional failure to respond to the throttle might be ascribed to a sticking auxiliary air valve or similar temporary derangement of the carbureter that would radically alter the character of the mixture. It does not seem possible that the fluid you describe as oozing from the cylinder cap can be oil; it is water from the circulating system, as the cap in question closes the water-jacket, this opening being left in order to permit of access to the walls of the water-jacket, so that it may be cleaned of sand and the like after casting. Such a slight leak as you describe can have no possible effect on the running of the engine. Remove the cap, clean the threads both of the cap and cylinder, and smear them well with litharge, then screw up again. This will undoubtedly cure the leak, and perhaps merely a half a turn or so may prove just as effective without removing the cap at all. Try tightening the cap a bit, and if the leak still persists, give it the above treatment.

Regarding the short circuit you speak of, we judge from your description that the coil-maker has provided a sort of over-load relief. In other words, there is a gap in the secondary circuit presenting a greater resistance than that of the spark

plug, but not too great for the coil to safely bridge. Should the spark plug points be too far apart, or for any other reason a resistance greater than that ordinarily presented by the plug be interposed, as by the falling free of one of the plug cables, the spark will immediately bridge this relief gap and the coil will not damage. This is because of the fact that if the resistance between the two exterior terminals of the secondary winding is greatly in excess of the capacity of the coil to bridge, the current is apt to break down the insulation by jumping from layer to layer, usually termed "burning out." The fact that there is an occasional short circuit at the point you mention seems to be indicative of dirty plugs, points too far apart, or some similar cause that has raised the resistance of the gap considerably above that for which the coil was designed, and the safety device has come into play. Clean or adjust the plugs, or replace them with new ones, and note the effect by running the engine and watching for a short circuit at the point in question. If it still continues, inspect the wiring for breaks. It is possible that something has struck the lever you mention, causing it to come nearer to the terminal in question, so that the safety gap is now much less than it was as originally designed. Spark-plug points are seldom set more than 1-16 inch apart, and usually less. Probably 3-8 or 1-2 inch would be about correct for the safety gap, as this would represent a vastly greater resistance than that of the plugs, but would still be within the safe capacity of the coil. The necessity for safeguarding the coil as well as the why and wherefore of it appear to constitute something that even well-versed autoists are not conversant with in very many instances. We should like to hear the outcome of your investigation.

Some Piston Ring Considerations.

Editor THE AUTOMOBILE:

[576].—What is the theoretically-perfect form for an efficient piston ring, and can it be realized practically? If in your answer you can give something bearing on the comparative merits of the different constructions most used, I am sure that there are others of your readers besides myself who will appreciate it.

Jamestown, N. Y.

MILTON HOWELL.

A theoretically perfect piston ring would bear evenly and with the same pressure against the cylinder wall all the way around. Such a ring is impossible to make practically, though excellent approximations are secured by several methods. Of the principal types of rings in common use, it can be safely said that any of these, when well made, are thoroughly serviceable. What is probably the commonest type, the eccentric ring, theoretically should taper to an infinite thinness at the point where it is split, as only by such design could it be possible to secure even springing all around. Practically, of course, considerable thickness must be left, even at the thinnest point, to fill the groove and provide the necessary strength. By hammering the inside of the ring—a common practice—the springiness is reduced and increased at such points as require it. Rings made very light and small, and held in contact with the piston wall by supplementary springs of one sort or another placed behind them, have often proved capable of giving better service than any other kind.

HOW A STANLEY AGENT FEELS ABOUT IT.

Editor THE AUTOMOBILE:

[577].—I have noted several editorials and remarks in your magazine to the effect that "freak sprinters" are doomed and that the failure of the whole Ormond meet this year, was a failure largely owing to the entrance of the Stanley cars, which would seem to be rather a good ad. for these cars if the 60, 90, 120 and 200-horsepower cars were afraid to enter in competition with the 20-horsepower Stanley cars.

Granting that the Stanley racer was to some extent a freak, if you strip off the elongated aluminum cover, and put on an ordinary body, it does not come as near being a freak as most of the freak gasoline cars entered, which are absolutely no use except on a Vanderbilt cup course or on a stretch of beach like Ormond, and I'll venture to say that the so-called Stanley freak could get out on an ordinary road and give some of those 120-horsepower racing freaks cards and spades and beat them out.

I was at Ormond two years ago when Louis Ross cleaned out about everything there, and if there is anything that comes any nearer being a freak than Mr. Bowden's eight-cylinder "Flying Dutchman," I'd like to see it, and I noted that many of those large gasoline racing freaks had about all they wanted to do to get up the hill off the beach, they were geared so high.

Then, too, last season, the 200-horsepower Darracq was a racing freak purely and simply, and could hardly have stood on a trip over an average country road.. I saw Mr. Croker's car after it was wrecked, and from the pictures I have seen of the Stanley racer I notice that Croker's car was more of a wreck than the Stanley, notwithstanding the fact that some of the papers have said it was so light that it all went to pieces.

When you are belittling steam and the Stanley cars, and giving reports of the races, why do you not give the reasons when a Stanley was compelled to withdraw; but instead, you say "They seemed to lose power and pulled out," when you know very well or could have known that in one instance the check to the gasoline pressure pump got stuck, consequently the fire would not give them the required steam, and when a fully equipped touring car is driven a mile in something like 40 or 45 seconds, I think it was, you hardly notice it, but still continue to stick to it that these cars are of no use but to sprint. How about the 15-mile race last year, when a Model H car beat everything and made it in 13:42.5? How about the five miles which Stanley made in 2:47.1-5? Two years ago Mr. Ross said the only mistake he made was that he did not enter in the 50 and 100-mile race. He could have stopped and taken water and then won out. This year they had hard luck on those races, but the cars entered were in no sense freaks, and I contend that the most of the large gasoline cars with the seat on the rear axle and geared only for a level are absolutely useless except on a race track, and are in a way as much freaks as the Stanley racer.

Personally I think freak racing either with steam or gasoline cars amounts to little, but if you are going to bar out a steam freak, be square and bar out gasoline freaks as well.

E. A. BRODIE,

Agent for Stanley Car.

Burlington, Vt.

ANOTHER CONTRADICTION FOR MR. BOOREAM.

Editor THE AUTOMOBILE:

[578].—Referring to letters regarding crankcase breathers in the issues of "The Automobile" of December 13 and January 17, I herewith submit a trigonometrical proof that you were right and J. F. Booream was wrong, as to the angularity of connecting rod affecting the volume contained in crankcase, etc. As an actual fact the volume would vary over 78 cubic inches in a four-cylinder engine 5 x 6 inches, with 10-inch connecting rods. For instance, let ABCD be the circle described by crank;

and OB equals r equals length of crank; and AA' equals BB' equals CC' equals l equals length of connecting rod; and A & A', B & B' and C & C' represent respectively the positions of crank and piston wrist pin at bottom of stroke, after crank has revolved 90 and at top of stroke. Let α equal the angle piston rod makes with vertical, when crank has revolved through first 90°. Describe arc B'K through B' with B as center. Draw horizontal lines E B' and H A' through B' and A'. Then AO equals HK equals r equals vertical distance traveled by crank in revolving through first 90°.

And A'B' equals distance traveled by piston during same period. But A'B' equals HK minus EK. And EK equals $l \text{ versine } \alpha$. Therefore A'B' equals $r \text{ minus } l \text{ versine } \alpha$.

Now as long as l and r bear some finite relation to one another, "l versine α " must have some finite value;

And, as total distance traveled by piston from bottom to top of stroke is equal to 2r:—

It is plain that the distance traveled by piston while crank is revolving through the second 90° is greater than the distance traveled while crank is revolving through first 90°. The difference is equal to $2l \text{ versine } \alpha$.

To put the above in other words: In a four-cylinder engine, the displacement due to the downward moving pistons is not at all times compensated for by the upward moving pistons.

New York City.

W. C. STEARNS.

AUTO CABS IN THE GREAT WORLD CENTERS

By W. F. BRADLEY

NEW YORK, Paris, London, Berlin, all have their transportation problem, and have all in a greater or less degree called upon the automobile for a solution. Geographical and topographical conditions as well as local custom vary the problem in every center, and call for correspondingly different treatment. New York is compact, dense, bustling; its system of elevated, surface and subway cars—the most complete in the world—is perfectly suited for its peculiar conditions. London is vast and varied, has a tremendous area open to similar treatment to that of New York, and a center so dense that surface cars are an impossibility, hence a special treatment of the transportation problem. Paris is compact, easy-going, combines pleasure and business in about equal proportions, and has a well-developed esthetic trait.

The Origin of Motor Cabs in Paris.

At the present time Paris and London make an almost equal though widely differing use of the automobile for public transportation service. Four years ago the only public automobiles in Paris were a score or so of gasoline cars, which hung about the national opera house, and a small number of electric cabs somewhat similar to those at present in use in New York. The gasoline cars were ancient models, frequently owned by their drivers, had no definite scale of charges, and were mostly patronized by visitors to the city. Some of the drivers were proud of the antiquity of their machines, and if you were inclined to listen would tell a wonderful story of Daimler's personal connection with the vehicle. The electrics were heavy, slow and never found favor with the public.

Paris has always been well supplied with horse cabs, light vehicles, open in summer, closed in winter, pulled by a lean

horse and driven by a fat cabby, for thirty-five cents, including tip, you could travel from one end of the city to the other. They were so cheap, so handy, that everybody used them, frequently in preference to omnibuses and subway trains. The taximeter system was introduced, fares being made proportionate to distance traveled, but the scale still being kept very low. After a brief dispute the scheme was a huge success, the public and drivers alike asking for its extension. The motor cabs adopted it and increased a little in popularity. About eighteen months ago a company placed on the streets of Paris a number of Renault automobile taximeter cabs. From the outset they were an unqualified success. From 100 their numbers were increased within a few weeks to 250, and in a few months' time they will number about 600. Alive to the possibilities of this branch of automobiling a dozen or more firms produced automobile cabs and offered them to the cab companies and other corporations. The offers were not all accepted, many of the imitators being inferior to the original article. At the present time, however, in addition to the Renault cabs there are a small number of Panhard, Chenard & Walcker, Unic, and Bayard-Clement machines specially built for this service. In addition a number of schemes are afoot for the increase of automobile cabs, and several of the most important French factories are busy on chassis for cab service. Darracq is at present perfecting a cab, to be turned out in huge series; Panhard is doing the same, and the Bayard-Clement people have just produced a special chassis which will be extensively adopted in more cities than Paris. Judging from the number of cabs now on order, and the inquiries afoot, the five or six big companies operating horse cabs will in two years time have entirely transformed their service and the public horse-drawn cab will no longer exist. On a moderate estimate, Paris alone will have

RENAULT TAXIMETER AUTO CABS IN FRONT OF THE HOTEL SCRIBE ON THE BOULEVARD DES CAPUCINES, PARIS.

NEW BAYARD-CLEMENT CAB CREATION.

eight or nine hundred motor cabs at the end of the present year. The Renault, which inaugurated this change, has a two-cylinder engine in one casting, 75 by 100 bore and stroke, mechanical valves, automatic carbureter, ignition by magneto and sparking plugs, thermo-syphon water cooling, and is rated at 8 horsepower. Simplicity and accessibility are two of the most valuable features of this car. The Renault method of placing the radiator behind the engine has special advantages for cab work. There are no control levers on the steering wheel, the speed of the engine being regulated by a small controller on the dashboard, from three to twenty miles an hour being thus obtained. The pedals are but two in number, one operating the clutch and brakes, the other being an accelerator. There are three speeds ahead and reverse, transmission is of sliding gear type, and drive through propeller shaft and rear live axle, as in all Renault cars. The dimensions of the chassis are special; the rear width is 35 inches, the front width 25 inches, the track 54 inches. This gives an enormous steering angle, and the car can be turned round in a 23-foot street without the use of reverse gear. A landaulet body is carried, with ample room for two people on the rear seat, and place for two more on a folding seat. In a moment the cab can be transformed from a completely closed to an open vehicle with glass front. This type has been found the most suitable and has been adopted by all the companies.

Bayard-Clément Produced an Excellent Model.

One of the most interesting of the Paris cabs is one just produced by the Bayard-Clement Company. The Compagnie Générale des Petites Voitures à Paris, the largest and oldest of the Paris cab companies, asked for a chassis to replace their horse vehicles—cheap, simple, easily dismantlable, and impossible to put out of commission even by unskilled horse-cab drivers. It was a difficult bill to fill, but the company filled it. The chassis has a four-cylinder engine, 75 bore by 90 stroke, giving 14 horsepower at 1,200 revolutions, the four cylinders, gearbox and upper part of crankcase being a single casting. The entire block, motor, clutch, gear box and pedals, is attached to the chassis by three-point suspension.

The lower part of the crank case remains permanently attached to the frame, forming a huge oil tank. By withdrawing six bolts the entire motor, together with the crank shaft and the oil pump, can be dismantled. If repairs are necessary, the chassis can be relieved of its motor in half an hour. Thirty minutes more and another engine can be put in its place, for no adjustment is necessary on the chassis, and there is no delicate alignment of crank shaft and gear box. To obtain the maximum of accessibility the radiator has been placed behind the engine and against the dashboard, as in Renault machines. Water circulation is by thermo-syphon; the water tank forms a frame around the radiator, and a draught of air is assured by a large fan. Ignition is by Lacoste magneto, the carbureter is automatic and has its air inlet completely surrounded by the exhaust; lubrication is of force-feed type, regulated by a small lever on dashboard; clutch is leather-faced cone type, with a special arrangement allowing the spring

to be quickly changed; transmission is through sliding gear, giving three speeds ahead and reverse, with shaft drive. A remarkable feature is that the bevel gear, differential and rear axle housing is a special one-piece stamping. Another new feature is that the driver is seated at the left-hand side, the brake and change speed levers being in the center. The body work is similar to the standard type in use in Paris, a speaking tube communicates with the driver, and of course the taximeter is fitted. The Darracq cab is now undergoing tests, and particulars are not available for publication. It has a single cylinder engine, 90 by 120 bore and stroke, developing 8 horsepower, and shaft drive. The Panhard cab is a three cylinder of about the same horsepower; the Chenard & Walcker, a number of which have been bought by Paris cab companies, is a 15-horsepower four-cylinder vehicle.

Motor Cab Fares Are Not High.

In fixing a scale of charges for the automobile taximeter cabs account had to be taken of the low scale in vogue for horse-drawn vehicles, the minimum fare for which is 15 cents for any distance up to 1,300 yards. The automobile cab fare for two people is 15 cents for 984 yards. A one-mile journey would cost 20 cents, for after the first 984 yards the rate of travel is but two cents per 328 yards. No wonder with such low rates, quick travel, comfortable vehicles, a mechanical instrument for registering the exact fare, and precluding all possibility of dispute with the driver, that the cabs should have been a success. The drivers are paid a fixed daily wage, and in addition receive a certain percentage of the takings above a minimum amount. Each man buys his own gasoline, an equitable allowance being made off the daily takings for this purpose. The allowance has been arrived at, after very exhaustive tests on various kinds of city runs. By careful driving a small sum can always be gained on the fuel allowance.

London has devoted all its attention to the development of the motor omnibus, and has been so active in this direction that there are now about one thousand buses in service. London traffic is too dense to allow street surface cars in any but the suburban districts, and the horse-drawn bus remained the only surface communication until it was ousted by its gasoline rival. Automobile cabs in London are rare. They, as well as the horse-drawn vehicles, are operated on a system of distance fares, as in New York. If strictly enforced, the fares would not be excessive; but it is rare for them to be applied justly, and whenever a dispute occurs, it is the traveler who pays the bill. The taximeter system is not used; its mere mention has always called forth a strong protest from the autocratic London driver. After Paris, cabs are more common in London than any city in the world. English capitalists have realized the possibility of replacing the horse vehicle by the gasoline cab, and the next two years are likely to see a change as great as that just accomplished in the

CHENARD & WALCKER CAB A SPEEDY ONE

'bus service. Five hundred Renault cabs, similar to those in Paris, are already on order, and will be running this year, Darracq is said to have booked a big order for their new type of cab, Bayard-Clement is negotiating, and several of the smaller French manufacturers are endeavoring to place series of cabs with London syndicates. All these vehicles will be operated on the taximeter system, and their introduction on such lines will sound the death knell of the old-time horse vehicle.

Only a few weeks ago a new Public Carriage Order was passed by the British authorities making the adoption of the taximeter optional for London auto cabs up to June 30, 1907, and compulsory after that date. The scale of charges which will then come into force is such as will give the auto cab a distinct advantage over the horse vehicle, and with a compulsory taximeter system no one will take a horse cab when a motor vehicle is available. The scale of charges for the automobile cabs is the very moderate one of 17 cents for the first mile and 4 1-4 cents for every subsequent quarter. Thus, a two-mile journey for two passengers would cost

per 656 yards, and 2 1-2 cents for each additional 328 yards, the charge for a one-mile journey being approximately 27 cents.

What New York Is Going to Do.

Compared with European cities, New York cab fares are excessive, even when allowance has been made for the all-round higher cost of living in this city. If the correct legal fare were always applied, there would not be much ground for complaint; but everyone who has made acquaintance with the New York cabby knows that he nourishes a supreme contempt for legalities. Motor cab service has been confined to electric vehicles of a type that Paris and Berlin discarded a couple of years ago. A comparison of fares is practically impossible, owing to the point-to-point system in use here. The rate given by the only company operating electric cabs in New York is \$1.50 for any point between Thirtieth and Fifty-ninth Streets, approximately a mile and a half. The price for the same distance in a Paris gasoline taximeter cab would be less than 30 cents, and for

LONDON AUTO CABBIERS ON TRAFALGAR SQUARE. THEY DO NOT YET KNOW THE BENEFITS OF THE TAXIMETER.

34 cents. The law allows the auto cab companies to charge for luggage and extra passengers, but, as is the case in Paris, the companies do not intend to avail themselves of this permission. The taximeter as used in all European cities is an ingenious instrument which registers the amount due for either distance covered or time occupied. On starting a journey the driver lowers a small metal flag, and instantly 8d. or 75c.—whether you are in London or Paris—appears on the dial. If the cab stops on its journey, or moves at less than six miles an hour, a clock within the instrument comes into operation and advances the figures a mile per ten minutes. It is impossible to hire an auto cab by the hour, but whether the vehicle is moving or standing still the charge will be the same. Very extensive tests made in Paris have proved that on one-hour journeys, whether the cab was standing still, running at a normal speed, or alternately racing and crawling to suit traffic conditions, the fare was practically the same.

Germany was not very successful in her first attempts to replace horse cabs by motor-driven vehicles. Electricians first made their appearance at Cannstadt, but were soon found to be too costly. Berlin, a little later, adopted electric-driven cabs, with hardly more satisfactory results. Finally, the same company placed a number of gasoline cabs on the streets, with rather more success. The Berlin taximeter cab tariff is 17 1-2 cents

this amount two people could be carried as against only one in the home vehicle. There is obviously room for improvement here, and improvement will not be long in coming, for a company is at present being floated to operate gasoline automobile cabs in New York on the taximeter system as known in Paris. Two hundred Renault cabs are at present under construction, and will be running on New York streets within twelve months. The cars will be entirely built abroad, and will be similar in every respect to those in use in Paris and London. Lest visions of a paltry quarter should arise, it is necessary to mention that the Paris cabs will not bring the Paris fares with them. Nevertheless, the promoters of the scheme assure that a lower tariff will be adopted than any at present in use in New York for either horse or mechanically driven cabs. The use of the taximeter, too, will make the cabs immensely popular with the public. There will be no haggling before the journey, nor any bad words at the end of it. Once adopted, the old type of cab will disappear from the streets as rapidly as the horse car gave way before the electric street car. Other important French firms, having produced a cheap and economical type of cab, are endeavoring to find an outlet in New York. Home constructors are looking into this matter, too, foreign systems having been closely studied, and developments are likely to proceed with activity

HIGHER REGISTRATION FEES FOR MASSACHUSETTS

BOSTON, Feb. 11.—The recess committee on taxation of the Massachusetts Legislature, which was appointed last year to consider methods of increasing the revenues of the State, and which held hearings through the summer and fall months at the State House and in various other places, has presented its report. It deals with the question of increased fees for the registration of automobiles, to secure funds to make repairs on the State highways, at some length, and presents with its report a bill which, in effect, is for a graded system of registration fees.

The bill provides, in brief, that all automobiles and motor cycles, except ambulances, fire engines and road rollers, shall be registered with the Highway Commission. In applying for registration the owner shall state the name of the maker of the automobile, number and size of cylinders, character of motor power and the horsepower. Motor cycles, express wagons, trucks and traction engines and other vehicles used solely for business purposes, shall be registered for \$2 each. The registration fee for other automobiles shall be determined by the Highway Commission, which shall take into consideration the damage which such automobiles cause the State highways and the amount of revenue required to repair the damage. It is provided that the registration fee shall not be in any one year less than \$5 nor more than \$15.

The bill further provides that upon the transfer of any automobile in the \$2 class its registration shall expire. An owner of an automobile in the class for which the registration fee is \$5 may be granted a new registration on transfer of his car for \$2. If the owner transferring the car does not give the Highway Commission notice within ten days his registration expires.

Another provision in the bill is that the registration of every automobile in the \$5 or over class shall expire July 1, 1907. After that date the registrations expire on the first of March following the time they are registered. Continuing, the bill reads: "The said commission shall, on or before the first day of February in each year, determine the fees to be charged for such registrations and shall give written notice thereof to each owner or person in control of an automobile as evidenced by the records of its office and subject to such registration fee." Concerning cars from out of the State the bill cuts down the time they may be operated in Massachusetts without a Massachusetts registration to two days.

In section two of the bill the fee for a manufacturer's or dealer's registration certificate is increased from \$10 to \$25. The third section provides that the fees received under the provisions of this act, together with all other fees received by the Highway Commission from automobiles, shall go to the State highway maintenance fund, which is to be used for the maintenance of the State highways and for carrying out the provisions of the act, in sums appropriated by the General Court. The bill contemplates the possibility of the Highway Commission establishing branches for the purpose of registration in other cities, for it provides that application for registration may be made to the Highway Commission, or any agent designated for the purpose.

In its report accompanying the bill the committee says in part:

"We have found a widespread desire for change in the present license or registration system of automobiles. At the various hearings of the committee arguments were convincing and unopposed that these machines have caused and are causing unusual and alarming damage to our improved highways; and that unless steps are quickly taken to check this evil or provisions made for their frequent repair, our State highways must soon lapse into furrowed stretches of broken stone. The occasion for this almost universal complaint is that the roadways of the State, lately constructed at large expense by contributions in way of

taxation from all property, are rapidly being desurfaced and laid waste by this particular class of vehicle, the loose and projecting stone left uncovered rendering the road a source of discomfort to every variety of travel, and in some instances almost impassable. The rapid development of these machines and their increased use upon our improved highways have proved so injurious thereto as to convince those charged with the construction and repair of highways that such sums as the Commonwealth has thought proper to annually appropriate for maintenance will fall far short of the amount needed. Even were the modest fees now required for registration of automobiles devoted wholly to repair, the sums so received would prove wholly inadequate to make good the mischief they accomplish. These conditions have been apparent to owners of automobiles as well as to others; and it has been gratifying to the committee to observe that owners have not opposed additional registration fees proportionate to the damage caused, provided the sums thus received be expended in improvement of roadways. At points adjoining neighboring States, notably in the Berkshires, complaint is made that the injury is caused or largely aggravated by foreign machines, their owners crossing the border to enjoy the beauty of our scenery and the freedom of our roads for a few days only, rendering no return for the ravages of their powerful, swiftly moving touring cars. While the committee realizes that the presence of these strangers is not without some compensating return, it believes a stay beyond the reasonable length required for passage through the State should subject the owner to burdens similar to those imposed upon our own citizens operating cars.

"The Highway Commission has experimented in various ways and with various kinds of rock to produce a good road surface proof against speedy disintegration, but thus far has been unable to produce a surface sufficient to withstand the severe strain of the automobile. This machine, to gather and maintain its headway, seems to break into and loosen the binder, so called; clouds of dust follow in its wake, and are blown away. With the flight of each machine similar results follow, and the roadway is denuded. The Commission has also experimented with oil and tar to preserve the surface, but not as yet with results wholly satisfactory. While it is hopeful of solving the problem ultimately, yet in any event the process must prove an expensive one, the requirement for which is largely due to the presence of the automobile."

HOPES FOR BETTER PENNSYLVANIA LAW.

HARRISBURG, PA., Feb. 11.—Senator Crawford has introduced in the Pennsylvania legislature a new motor vehicle law. It provides for the annual registration of motor vehicles at a charge of \$3, the State issuing tags as at present. Operators, other than the owner, must become "licensed drivers," paying a fee of \$2 and wearing a badge when driving. No person under the age of 18 being permitted to operate a car under any circumstances. Non-residents whose cars display tags indicating the State by which they are issued are exempt from the registration and license provisions for a period of ten days.

The rate of speed permitted is a mile in four minutes where houses are less than 100 yards apart, reducing speed to a mile in six minutes at curves and cross streets. A mile in two minutes where houses are more than 100 yards apart, reducing to a mile in four minutes at curves, cross roads, descending steep hills and passing other vehicles. This is limited by the usual provision forbidding any speed greater than is safe, considering road and other conditions. No local ordinances fixing lower rates of speed are permitted except in cases of parks and boulevards, where, however, the rate shall not be less than that permitted horse-drawn

vehicles and the erection of signs is required. Physicians answering emergency calls and vehicles used by the military, police and fire department are, when in the performance of duty, exempt from speed restrictions.

The customary regulations as to brakes, lights and signal device are included, and operators of motor vehicles are required to give such reasonable notice of their approach as the safety of the public requires, and in meeting animals that appear to be frightened or unmanageable to stop without waiting for signal to do so. An effort is made to place motor vehicles on exactly the same basis as horse-drawn vehicles in the use of the highways and to induce the displaying of a light by all vehicles.

The penalties for the violation of the law are as at present, except that the operation of a motor vehicle by any intoxicated person renders him liable to a fine of \$100 or 30 days' imprisonment.

The rules of the road are plainly indicated and the bill is a decided improvement on the law at present in force. It has the approval of the State Highway Department and is indorsed by the Pennsylvania Motor Federation, as while it protects the public in their use of the highways it will tend to free automobilists from the petty persecutions of the past two years. Should this bill become a law the present method of licensing would continue in effect until the end of the current year.

MISSOURI LEGISLATION UNCERTAIN.

JEFFERSON CITY, Mo., Feb. 9.—Missouri automobilists, at least those of the Automobile Club of Kansas City, have given up the ordinary methods of securing legislation favorable to them and have employed an attorney to represent them at the capital of Missouri. The automobile which was abroad on the streets of this picturesque city to demonstrate to rural legislators the delights of motoring, has been sent back to St. Louis, where it should have remained in the first place. It only gave the fellows who got fewer rides than the others a chance to line up against a more liberal law.

There was a hearing before the joint committee of jurisprudence of the house and senate. From Kansas City there were C. C. Madison, R. J. Ingraham and O. A. Lucas, attorneys for the club, and H. G. Blakeley, secretary of the club; from St. Louis, Roy Britton, secretary of the St. Louis Automobile Club, and Judge James Seddon. All of these argued in favor of the bill, while Representative Brooks, who has a bill requiring owners to give bond before being permitted to operate their cars, spoke against it. The committee did not agree on a report. A Kansas City member, who had been lined up, went over to the opposition. The Kansas City club finally realized that the bill would have hard sledding unless intelligent work was quickly directed toward it, and they began by getting a good lobby of one man. The country members, except those from St. Louis county, are generally liberal, but the St. Louis county members claim the speed nuisance has been so intolerable that it must be checked.

Further interest in the legislature has resulted from the passage by the house of a bill permitting the levy, by counties, of a special tax of 50 cents on the \$100 for road and bridge purposes. The bill is a resolution and will permit the voters of the entire State to vote upon the matter as an amendment to the State constitution.

Other things in the way of Missouri legislation that will interest autoists include a bill by Representative Botsford. It allows a speed of 25 miles in the country, but if a horse is frightened, the name of the autoist must be left with the horse driver. The most novel clause of the bill, however, permits cities to set aside certain streets where speed tests may be allowed at certain hours.

Another bill, by Representative C. A. Willard, of St. Louis, proposes to create the office of State motor vehicle commissioner, who shall have authority to appoint as many deputies as necessary to enforce the speed laws in the different cities of the State. The office of commissioner is to be appointive by the governor and to pay \$2,500 salary annually.

EX-PRESIDENT FARSON ON ILLINOIS LAW.

SPRINGFIELD, ILL., Feb. 11.—Uniform auto regulation in the State of Illinois before the end of this year is predicted by John Farson, ex-president of the American Automobile Association. This is indicative of the spirit which is causing automobilists throughout the State to make a concerted demand on the general assembly for better laws. If the present laws relating to automobiling were strictly enforced, Mr. Farson says, not a man in Illinois could afford to indulge in driving. Every city, town and village in the State, he asserts, has practically a different set of ordinances relating to automobiles, and it is only due to the leniency of local authorities that the ordinances are not enforced. Illinois should give automobilists a uniform speed law—one which would enable drivers to know just what speed can be made in any part of the State.

"At present the speed limit is absurd," said he. "An old lumber wagon can make better time than eight miles an hour, and that is the speed which the authorities demand we shall not exceed. Under proper regulations and conditions, twelve to fifteen miles an hour in the city and twenty miles an hour in the country would be about right. At the present time in Chicago there are a number of different laws affecting speed. The city has one ordinance and the park boards each have different rules, which, if violated, arrest and fine immediately follow. I know one of the park boards has a rule that automobiles must toot their horns at crossings, and another has an ironclad regulation that if the horn is tooted at crossing the perpetrator shall be arrested at once. Of course, this all goes to show that a great many reforms must be made. The bill which is now before the legislature takes all these into consideration, and I believe they will be acted upon favorably. Other States are beginning to see that the automobile is bringing good times and prosperity with it and they are grateful in many ways. In Illinois about the only persons who think of the automobile as a sign of prosperity are the country constables."

VERMONT'S LOW RATIO OF AUTO ACCIDENTS.

ORWELL, VT., Feb. 11.—A Vermont paper—the *St. Albans Messenger*—has compiled statistics which show that the automobile killed only one person in Vermont in 1906, while horses, in various ways, were responsible for fourteen violent deaths. Of course, auto and horse are not in the strict ratio of 1 to 14; but, laying aside mathematical accuracy, one death in twelve months in a population of over a third of a million is not a positively murderous record to chalk against the chauffeur.

Inasmuch as the Vermont legislature has not seen fit to make automobile laws in accordance with the views of Colonel Joseph Battell, of Middlebury, who is well known throughout the State as an ardent hater of automobiles and an equal lover of the horse, autoists now commend his efforts in the direction of abolishing electric cars, railroad trains, firearms, poisons—in fact, anything that ever causes death by accident—except the horse.

REGISTRATION LAW IN KANSAS.

TOPEKA, KAN., Feb. 11.—A bill providing for the registration of automobiles has passed the Kansas house by a vote of 65 to 15 and is now in the hands of the Senate. It provides that all automobiles in the State of Kansas shall be registered with the secretary of state, the registration fee being two dollars. This regulation, does not apply to traction engines, bicycles and tricycles. In making the declaration of ownership, the automobilist's name and address, the seating capacity of the car, the maker's name and color of machine shall be given. Registration numbers shall be carried in the front and rear, shall be in figures not less than six inches high, of proportionate width, and of a color to render them easily distinguishable. Penalties for violation of the act, which shall come into operation from May 1, 1907, are a fine of not less than ten dollars nor more than fifty dollars.

FEBRUARY ACTIVITIES OF THE AUTO CLUBS

Hawaii Prepares for its Floral Parade, February 22.

HONOLULU, HAWAII, Feb. 1.—At a meeting of the Automobile Club last night the matter of the annual floral parade came up and aroused a great deal of enthusiasm. Preparations are being made to eclipse last year's affair, and the fact that there are now 106 automobiles on the island instead of fifty-five, as was the case a year ago, promises well for the success of the parade. E. F. Bishop, on the part of a number of autoists, accepted the invitation of the parade committee of the club, requesting the co-operation of individual owners.

A number of other subjects were taken up at the meeting which was well attended, after the matter of the floral parade had been disposed of. Chief among these was the question of good roads. Chairman McCandless, of the good roads committee, reported the result of an interview he had had with Supervisor S. Dwight, who said that attention would first be paid to putting the roads along the water front in good shape, after which King and School streets would be looked after, while the other roads about the city were to be put in shape and the damage caused by the recent storm repaired as soon as possible. It was his ambition to secure at least \$15,000 a month for road work and in this he was supported by the other supervisors.

Mr. McCandless' report was followed by a general discussion of the road question. The manner in which oiled roads had withstood the severe storms was cited in their favor, and the use of bitumen was also suggested, a test strip of this type of road having been laid on Queen street and proven quite successful, its only drawback being its heat holding quality. It was decided to extend an invitation to Samuel C. Lancaster, of the good roads branch of the Department of Agriculture, who is shortly to deliver a series of illustrated lectures on road making throughout the West, to come to Honolulu.

New Jersey A. & M. C. Preparing for Endurance Run.

NEWARK, N. J., Feb. 11.—At a meeting of the board of governors of the New Jersey Automobile and Motor Club held last week, initial steps were taken for the first annual endurance contest of the club, which according to present plans will take place sometime this spring. The matter was thoroughly discussed at the meeting and a committee was suggested to look after the details of this event. H. A. Bunnell, secretary of the club, has been named as chairman of the endurance committee, but other members of the committee have not yet been selected, as it was not deemed advisable to select the other names until later, when it can be learned definitely those members who will be able to do the work that will fall to this committee.

It is expected that within a few weeks the committee will be in working order. Every member of the club is in favor of the contest, and there will be ample support, even so far as contributions for prizes in silver cups to winners in the big event.

The committee's real work will be in selecting a suitable route over which the contest will be run, and rules to govern the contestants.

National Association of Autoists for Canada.

MONTREAL, Feb. 11.—Rumor has it that a convention of automobilists embracing the Dominion of Canada, will be held in this city during the week of the Automobile and Sportsmen's Show, April 6-13, for the purpose of organizing a national association for Canada. The Automobile Club of Canada, whose headquarters are here, will take the initiative, and an organization similar in character to the American Automobile Association is likely to be formulated.

How Pittsburgers Secured the Signboards.

PITTSBURG, PA., Feb. 11.—The action of the Automobile Club, of Pittsburg, in securing the erection of road signs in Allegheny County, is one that should be followed by all other clubs in that as well as other States where similar laws exist. A year ago the club sent a committee to the county commissioners asking that the roads in the county be properly marked, as the few signs that were then in place were nearly all illegible. They were informed that under the existing laws the township supervisors were required to maintain such signs.

The matter was presented to the court and on the next quarterly return day constables were instructed to see that proper signs were erected at all cross roads. The following return day officers who failed to carry out the order of the court were given to understand that the matter must receive immediate attention, and by the time the county roads were in shape to use all cross roads were marked.

Every automobilist who has done any touring realizes the advantages of such signs and the annoyance of finding himself at an unmarked fork or cross roads. The desired results were secured in this case by the expenditure of perhaps an hour's time, and other clubs and individuals should profit by it and take similar action.

Aero Club Banquet Proposed at St. Regis.

NEW YORK, Feb. 11.—The first banquet of the Aero Club of America will probably take place at the St. Regis Hotel early in March. The speakers will include many prominent aeronauts.

For the Gordon Bennett International Aeronautic Cup Race at St. Louis in October next fifteen balloons have been entered, three each from the following clubs: Aero Club de France, Aero Club of the United Kingdom, Real Aero Club de Espana, Deutscher Luftschiffer-Verband, Aero Club of America. The entry is only one less than the number of participants in the race of 1906. If the three late Italian entries are accepted the 1907 race will have two more participants than its predecessor.

The Aero Club is now located at its new quarters, No. 12 East Forty-second street, where a comprehensive library of aeronautics is available to members. The telephone is 4321-38th. A committee will be appointed in the near future to prepare a set of rules, covering contests for the prize to be given for heavier than air machines without gas.

It is proposed to have a balloon ascension at Washington on Washington's birthday. Members have been asked to submit designs for a club flag.

The Cleveland Club's Ideal Road Is Assured.

CLEVELAND, Feb. 11.—Secretary Asa Goddard, of the Cleveland Automobile Club, says that the new road to be constructed under the auspices of the club will be one of the finest stretches of highway in the country. It will be built on the principles of the old Roman roads which have stood for centuries. The aim will be to get the foundation right; then, if the project runs a little short of funds, a little less money will be spent on the surface until such a time as it can be resurfaced. The foundation will be two and a half feet of rock with eight inches of chipped stone or coarse gravel on top of that. The new highway will take the place of the worst stretch of pike between Cleveland and Buffalo. The club has made another call on the automobile owners of Cleveland, calling attention to the deplorable condition of the highway east of Cleveland, and of the good work which the organization hopes to accomplish. Small donations are asked from all owners in this vicinity as well as from the farmers along the proposed route. Judging from the manner in which subscriptions come in, the success of the enterprise seems assured.

Long Islanders Want Eastern Parkway Extended.

BROOKLYN, N. Y., Feb. 12.—Entertainment in the shape of a smoker and vaudeville programme was the order of the evening at the Long Island Automobile Club last Friday, February 8. Members brought their friends and there was a large gathering, many of whom come in cars despite the condition of the streets. At the last meeting of the club a resolution was passed approving of the extension of Eastern parkway through Cypress Hills cemetery. The Jamaica Automobile Club is also lending its assistance in the matter and the aid of local politicians has been enlisted. Secretary Pierson, of the Long Island Club, has also been instrumental in taking up the matter of shipping autos abroad without crating, but as yet the steamship companies do not consider it practicable to do so. At the next meeting of the club, the Matheson, Oldsmobile, Winton and American Motors cars will be placed on exhibition.

Missourians Protest Against High Toll Rates.

KANSAS CITY, Mo., Feb. 9.—The Automobile Club of Kansas City, to which was extended an invitation to assist in the dedication of the mile and three-quarters-long viaduct which connects the two Kansas Citys and spans the Kaw river, refused to participate in any parade because the rates on the viaduct, which charges toll, are too high. The club informed the officials of the project that it could give no parade, as to do so would be practically to sanction the use of the viaduct. The rates the autoists object to are 35 cents for runabouts, the same as for a four-horse team, and a higher toll for larger vehicles. This is the only toll proposition in Kansas City and vicinity, except one bridge across the Missouri river, and autoists are preferring to tread their way among switchtracks in the bottoms until the rate is made reasonable for passage over the asphalted surface of the big bridge.

Marylanders Tour to Washington in May.

BALTIMORE, Feb. 11.—Now that the local auto show is a thing of the past, the Automobile Club of Maryland is preparing for some very interesting events to be held in the near future. Besides the H. M. Rowe Touring Contest, an endurance test to Washington will be held in May under the auspices of the club, which is now recognized as the great leader in everything automobiling south of the Mason and Dixon line. This test will attract a huge entry list, as every one of the local dealers will be interested to see that at least one of the cars he represents is sent over the rough and hilly roads that connect the two cities. A better course could not be found, as the road conditions are excellent for the purpose, and the course is well known to most of the local autoists.

Germantowners' Annual Banquet a Memorable Affair.

PHILADELPHIA, Feb. 11.—The handsome banquet hall of the Automobile Club of Germantown, was crowded on Friday night last, on the occasion of the organization's third annual banquet. Besides a full turn-out of members, many men prominent in city and State were present as guests, among them being State Senator W. C. Sproul, City Solicitor John L. Kinsey, E. T. Stotesbury, Peter Boyd, J. Hector McNeal, Isaac Starr, Jr., and others. The good roads feature was kept prominently to the fore throughout the evening, all the speakers having something to say on the subject. The Germantown organization is the sponsor for the proposed Philadelphia-Pittsburg highway, and has succeeded in interesting many prominent automobilists and legislators in the project.

Quakers Elect Charles J. Swain as President.

PHILADELPHIA, Feb. 11.—The first annual meeting of the Quaker City Motor Club was held at the club's quarters in the Hotel Majestic last Thursday night. Nearly 200 members were present. The election resulted in the choice of the following

officers to serve during the ensuing year: President, Charles J. Swain; first vice-president, George H. Smith; second vice-president, C. C. Fitler, Jr.; treasurer, A. T. Stewart; secretary, Theodore B. Creamer. The board of governors will be made up of Messrs. Swain, Smith, Fitler and Stewart, and G. Douglas Bartlett, E. C. Leeds, Nathaniel Hathaway, E. Hubbard Fitch, E. C. Johnson, A. E. Maltby, W. Wayne Davis, G. Hilton Gantert and I. D. Berger.

CLUB ITEMS OF INTEREST.

PHILADELPHIA.—The annual banquet of the Automobile Club of Philadelphia is scheduled for Friday, March 8, at the club house, 1409 Walnut street. A number of automobilists of national fame have been invited.

CLEVELAND, O.—The Cleveland Automobile Club is making great efforts to be a source of information to every resident autoist as well as to visitors. The name and address of every registered owner in Cleveland will be kept in a card index, this being but one of the many innovations along this line introduced by Secretary Asa Goddard.

WILLIAMSPORT, PA.—Organized with but forty charter members recently the Williamsport Automobile Club now has one hundred on its rolls and applications of fifty more waiting to be passed on. The club will devote its attention very largely to road improvement, and will hold a hill climb on Grampian Hill, which has about a 1,000 foot rise, as soon as the weather is favorable.

GRAND RAPIDS.—The local automobile club has not been the center of much enthusiasm during the past year, but new blood is now expected in the organization, and the club is making many plans to make up for lost time. If a new talked of University club is formed, it will probably become a part of that. A new club house has been planned at Cascade, 12 miles from the city.

CHICAGO.—A number of motor boat enthusiasts have got together here and formed the Illinois Motor Boat Club. The officers are as follows: Commodore, Theodore Weise; vice-commodore, M. L. Ames; rear-commodore, John Clark; secretary, W. H. Hungerford; treasurer, O. N. Hanson. The managing board is composed of the following: William Hoffman, Thomas O'Hearn, Edward Hester, Charles P. Crouch and William P. Weren.

BOSTON.—At the first fortnightly "smoke talk" of the season held by the Bay State Automobile Association, the subject was that of magnetos, and was gone into at some length by Harold H. Brown, who also spoke of the lessons of the New York show. The Bay State Association contemplates expanding and to that end extra quarters adjoining the present building have been secured; the rooms will be enlarged to provide for about seventy-five additional guests and a billiard room will be installed on the second floor.

THE MODERN HIGHWAYMAN.—From *Life*.
COUNTRY OFFICER: "Fifty dollars, sir! You were exceeding the speed limit."

THE AUTOMOBILE CALENDAR.

AMERICAN.

Shows.

- Feb. 18-23.....—Buffalo. Fifth Annual Automobile Show, Convention Hall. D. H. Lewis, manager, Teck Building.
- Feb. 18-28.....—Cleveland Automobile Show, Central Armory, Cleveland Automobile Trade Association. George Collister, manager.
- Feb. 18-25.....—San Francisco, Golden Gate Park Skating Rink. Automobile Show, Dealers' Association and Automobile Club of California.
- Feb. 18-25.....—Worcester, Mass., Automobile and Power Boat Show. Automobile Dealers' Association. F. N. Prescott, manager.
- Feb. 19-26.....—New York city. Madison Square Garden, National Motor Boat Show. Captain J. A. H. Dressel, manager.
- Feb. 25-Mar. 2...—Portland, Me., Second Annual Automobile and Power Boat Show, The Auditorium.
- March 2-9.....—Chicago, Second Annual Power Boat Show, Seventh Regiment Armory. W. C. Andrews, manager, 19 E. Huron St.
- March 2-9.....—Minneapolis, Automobile Show, First Regiment Armory, Minneapolis Automobile Dealers' Ass'n.
- March 4-10.....—Kansas City, Mo., First Annual Automobile Show, Convention Hall. Frank L. Woodward, manager, Willis Wood Theater Building.
- March 9-16.....—Boston Automobile and Power Boat Show, Mechanics' Hall and Horticultural Hall, Boston Automobile Dealers' Association. C. I. Campbell, mgr.
- March 18-16....—Omaha, Auditorium, Second Annual Automobile Show, Omaha Dealers' Association. T. Gillan, manager.
- March 18-23....—Providence (R. I.) Automobile and Power Boat Show, Infantry Hall. F. M. Prescott, manager.
- April 1-6.....—St. Louis, Mo., Automobile Show, Jal Alal Building, St. Louis Automobile Dealers' Association.
- April 6-18.....—Montreal, Canada, Second International Automobile and Sportsman's Exhibition. R. M. Jaffray, manager, 809 W. Notre Dame Street.
- April 8-13.....—Pittsburg, Pa., First Annual Show of the Pittsburg Automobile Dealers' Association, Duquesne Garden.

Race Meets, Hill Climbs, etc.

- Feb. 22.....—Los Angeles, Cal., Pasadena-Altadena Hill Climb, Automobile Dealers' Association of Southern Cal.
- Feb. 22.....—Atlanta, Ga., Hill Climb, Atlanta Automobile Association. F. E. Rushlander, secretary.
- Feb. 22.....—Washington, D. C., Aerial Race, Aero Club of America.
- May 30.....—Philadelphia, Hill Climb, Quaker City Motor Club.
- Oct. 19.....—St. Louis, Mo., International Aerial Race for the Gordon Bennett Prize. Aero Club of America.

FOREIGN.

Shows.

- Feb. 16.....—Turin, Italy, Automobile Show.
- March 1-16.....—London, Olympia Commercial Vehicle and Motor Boat Show.
- April 6-13.....—London, Agricultural Hall Motor Show.
- May 4-15.....—Madrid, Spain, Automobile Exhibition, Palace of Fine Arts, Royal Automobile Club of Madrid.
- May 15-26.....—Zurich, Third Annual Swiss Automobile Show.

Race Meets, Hill Climbs, etc.

- Feb. 23-27.....—Voiturette Contest, Automobile Club of Italy.
- March 20-27....—Nice (France) Automobile Week.
- April 1-16.....—Spring Wheel Competition.
- April 21.....—Targa Florio Tour (Sicily), Auto Club of Milan.
- April 25-28.....—Touring Contest, Automobile Club of Touraine.
- April 28.....—Chateau Thierry Hill Climb.
- May 24-27.....—Voiturette Contest, Automobile Club of Austria.
- May 29-June 1...—Irish Automobile Club Reliability Trials.
- June 3-12.....—Herkomer Cup, Automobile Club of Bavaria.
- June 14.....—German Emperor's Cup, Taunus Circuit, Imperial Automobile Club.
- June 24-29.....—Scottish Reliability Trial. Scottish Automobile Club.
- July 1-July 8...—Grand Prix, Automobile Club of France. (Exact date to be decided upon.)
- July 14, 1908....—Paris to London Aerial Race.

CALIFORNIA CLAIMS HIGHEST PERCENTAGE.

SAN FRANCISCO, CAL., Feb. 6.—It will doubtless come as a surprise to the average autoist to learn that California can boast of more automobiles in proportion to her population than any other State in the union, and the same thing is true of her chief city, San Francisco, which sheds some light on the keen interest taken in the forthcoming show to be held there in the newly erected Coliseum, from February 18 to 24, which has a floor space of 75,000 square feet, or more than that of the Garden in New York. Regarding percentages there is said to be one automobile owned in the country at the present time for every 566 people. New York State has one for every 210 people, while California has a machine for every 173 inhabitants. Chicago boasts of an auto for every 377 people, but San Francisco goes this better to the extent of having one for every 133 people. Many of the exhibits that graced the New York and Chicago shows have been sent on by a special train running on a passenger schedule. No efforts have been spared to plan as complete a show as any ever held in the country, and, what with the elaborate decorations and electric lighting, it is confidently expected that San Francisco's first effort will be in every way a counterpart of this season's shows in the East. The railroads have made a special rate of a fare and a third from any part of the State.

KANSAS CITY'S SHOW PREPARATIONS.

KANSAS CITY, Mo., Feb. 9.—Not only having the same decorations but the same designer to install them, Kansas City's show, which is to reign supreme during the week of March 4 to 9, will be a sort of replica of the Madison Square Garden exhibit. The show will be held in Convention Hall; the decorative scheme being modified in accordance with its size as it lacks about a third of the space offered by Madison Square Garden. E. H. Moriarty and J. H. Wittman, represented the Kansas City Automobile Dealers' Association at the Garden show in January, and Harry Houpt, head of the New York Thomas branch said to Mr. Wittman: "If you fellows do business like that at Kansas City, I'm going to wear my old clothes if I ever come West. If I wear a good suit I'll be traded out of it before I get back."

PITTSBURG SHOW TO BE HANDSOMELY DRESSED.

PITTSBURG, Feb. 11.—Green and gold will be the predominating colors in the general scheme of decoration at the automobile show in Duquesne Garden, April 7-13. The floors will be covered with green denim to show the brilliant colors of the cars by contrast. All the signs will be uniform in size and lettering, and will be suspended from the ceiling. The coat of arms lately adopted by the Pittsburg Automobile Dealers' Association is the seal of Pittsburg surrounded by an automobile tire. It will also be shown on the official button for the exhibitors. Cars varying in cost from a \$500 runabout to a \$10,000 touring car will be shown.

NORTH CAROLINA AGAINST AUTO THEFTS.

Senator George H. Bellamy, of North Carolina, has introduced a bill in the Senate of that State to punish the stealing of automobiles. The theft of vehicles is punishable, as it constitutes an infraction of the law, but heretofore automobiles have not been included under this statute. After covering fully what constitutes the larceny of an automobile, the bill concludes by imposing a penalty of four months' imprisonment upon anyone guilty of an infringement of the bill. As soon as the bill has been passed by the Senate its promoter will use his personal influence with Representative Morton to rush it through the House of Representatives. No opposition is expected.

The Western Power Boat Association has been formed by the motor boat clubs of Chicago as a nucleus. Every club in the Middle West will be invited to join.

The Boundless West Deserves a National Show. Chicago's show demonstrated unquestionably that as long as automobile exhibitions are necessary, one of a national character must be held in the West as well as in the East. These United States constitute a big country which is increasing in wealth and population in the West at greater speed than the present growth of the longer settled East. Furthermore, these Westerners are accumulating worldly possessions and in many instances they are realizing the capabilities and utility of the automobile more thoroughly than some of the conservative Eastern commonwealths where economy is more of a science than it is in the prosperous agricultural and mining States of the West. Distances are greater in the West and the necessity for covering them quickly is as much desired as anywhere else, for even the farmer and the ranchman consider a saving of time as a saving of money. In this growing popularity of the automobile in the boundless West there follows in its trail the unavoidable betterment of the roads and the consequent increase in land values. In the next decade it is safe to assume that many miles of first class highway will be built in Western States, and the automobile manufacturer is taking the West into consideration more than ever before in the distribution of his product. A national distribution of a particular make of automobile is as desirable as a national circulation for an automobile publication. Therefore, the Chicago show, with its large attendance of Western agents, would seem to meet a situation that requires a Western display of automobiles.

Promising Results from the Recent Fuel Test. While the fact that the internal combustion motor as at present in use in such large numbers for the propulsion of the automobile and the motorboat is capable of being run on almost any hydrocarbon sufficiently volatile to be vaporized, has long been known to those technically informed, the possibilities of fuels other than gasoline were but little considered in this country before the passage of what has come to be known as the "Free Alcohol Bill." Legislation of this kind is a thing of many years' standing on the Continent, by reason of which fact a great deal of data concerning the use of alcohol in the internal combustion motor has been collected. European makers and scientists have been experimenting with alcohol and alcohol engines for more than ten years past, and this fuel has come to have a very wide field of commercial application during that time. Nevertheless, there still remains a great deal to be done in this direction, and it is gratifying to note that no time has been lost in taking advantage of the opportunity here once it was presented.

Thus far the tests undertaken have been mainly of a popular nature, their chief object being to demonstrate that the automobile motor, as at present constituted, is capable of being run satisfactorily with fuels other than that for which it was specifically designed. This has been the case particularly with regard to the carbureter, a general impression prevailing that alcohol and gasoline are of such widely differing character that the same apparatus is not capable of handling both. That special apparatus is required in each case, when it is desired to obtain the highest degree of efficiency, goes without saying, but that the present-day motor and carbureter will run satisfactorily on kerosene or alcohol, in addition to gasoline, appears to have been demonstrated very conclusively by the recent test run, the results of which are given elsewhere in this issue. It is to be hoped that the matter will not be dropped at this point, but that further tests and experiments will be carried out.

Success That Awaits the American Automobile. According to the statistics compiled by the Department of Commerce and Labor, the value of the automobiles and parts exported from the United States during the year 1906 amounted to \$4,409,186, a gain of \$1,714,531 over the corresponding total of 1905. This represents an increase of something like sixty per cent., and this becomes 132 per cent. when compared with the total for 1904. These facts are sufficiently startling in themselves and quite in keeping with the rate of growth experienced at home, but they do not mean as much to the American industry as the fact that the total for 1906 fell short by but \$6,582 of equaling the value of the automobiles imported into this country from abroad during the same time. In 1901 there were only 314 automobiles manufactured in this country; during the same year France turned out 23,711, and a large part of them found their way to this country. Ever since then a goodly portion of all the automobiles made in France have eventually come into the possession of American autoists, not to mention those coming from other foreign manufacturers. In other words, Continental manufacturers were doing a large export business in automobiles with this country long before such a thing was thought of here—something that serves to form a basis upon which to make a comparison of the past year's showing as outlined above. Thus, it is not of such great import that the total valuation should reveal this remarkable increase as it is that it brings to light the fact that, for the first time, the American industry is almost on a par in this respect with its foreign competitors. In other words, that it has overcome an almost insuperable handicap in the short space of five years, and by so doing has gained the right to compete on even terms. The success that has greeted American machine tools and similar products in every part of the globe awaits the American automobile, and what the extent of its conquest will be but five years' hence is something that baffles the imagination to conceive.

DETROIT'S SHOW IN PROGRESS.

DETROIT, MICH., Feb. 13.—The most successful automobile show in the history of the trade in this city, if exhibits serve as a criterion, is that which opened at Light Guard Armory Monday evening. While not to be compared to either of the New York shows or the one that was held last week at Chicago, the Detroit exhibition is nevertheless a compact little affair, and many of the best cars of the trade are represented.

Present conditions simply point out the crying need of this great automobile city for a commodious assembly hall. The Light Guard Armory is the only available place at present to hold a show, and the capacity of this is so limited that it can scarcely take care of the needs of the local manufacturers. Indeed, with the press of outside concerns that are bent on showing here, it is impossible for even Detroit factories to show all the standard models, and some even have preferred to convert their retail stores into showrooms. The Ford people have taken no space in the armory, but are holding a private show at the downtown agency but a couple of blocks away. The Car de Luxe is another that was unable to get any space whatever, former patrons having been given first chance.

At that the local show has several attractions that have been sprung here for the first time—runabouts that came to light in the City of the Straits within the past few weeks. Notable among these is the Brush \$500 car, with solid rubber tires, which in design much resembles a light harness wagon, but of course is of much heavier construction. The Kermath Speedway is a new one to be shown here for the first time, and is a high-grade runabout, listing at \$2,000.

In the line of decorations the local show is very modest. Though plain, the entire armory and drill hall floors have been draped and decorated with the colors of the University of Michigan, maize and blue. The signs and displays are almost universal, and of the same colors with, of course, electric light attachments.

NECESSARY CHANGES IN FREE ALCOHOL LAW.

WASHINGTON, D. C., Feb. 11.—With a view to securing President Roosevelt's aid in bringing about certain amendments to the denatured alcohol law, Representatives Marshall and Hill, the authors of several bills on the subject now pending in Congress, recently held a conference with the President. The latter showed himself in sympathy with the demand for some changes in the present law and expressed the hope that Congress would enact the legislation which experience has shown is necessary. The original intention of the free alcohol law was to give the farmers of the country a chance to manufacture alcohol, but under the law and the regulations as they now stand the business is really thrown into the hands of capitalists or persons having ample capital. The Hill and Marshall amendments will enable the farmer, on a capital of a few hundred dollars, to establish his own plant and make alcohol for his own use as well as for sale.

THE KERMATH SPEEDWAY OF DETROIT, MICH.

DETROIT, MICH., Feb. 11.—The Kermath Motor Car Company, of Detroit, is the newest concern to enter the runabout field. The car is a light, high-powered runabout, and is known as the "Kermath Speedway." It was exhibited for the first time this week at the Detroit Show, and has several distinctive features, among which may be mentioned the radiator design, the location of the time gears and commutator, and the method of hanging the engine and transmission. The price of the Kermath is \$2,000.

EXECUTIVE COMMITTEE N. A. A. M. IN SESSION.

During the course of the Chicago show the Executive Committee of the National Association of Automobile Manufacturers held a meeting in the First Regiment Armory. At its close it was announced that the matter of holding a comprehensive test later in the season was deferred until the next meeting.

NOTED FRENCH AUTOIST DEAD.

A cable report from Paris announces the death in that city, at the age of forty-eight, of Léon Emmanuel Serpollet, a pioneer in automobile manufacture, and the best known exponent of steam as applied to automobile construction.

Léon Emmanuel Serpollet was born at Culoz, near the Swiss frontier, on October 4, 1858. College days over, Serpollet gave himself up to the study of mechanical problems, and was the first man in France to build a steam-driven automobile. He established a factory at Paris for the construction of light steamers, and was joined in 1899 by Frank Gardner, an American, the title of the firm being changed to Gardner-Serpollet. A huge business was done, Gardner-Serpollet engines being adopted by many large transportation, tramway and omnibus companies. Three years ago Serpollet brought out a new type of steam automobile, which met with much success. Last year he joined forces with M. Darracq for the construction of steamers on the Serpollet principle at the Darracq factory. A large factory was commenced adjoining the Darracq works at Suresnes, and has only just reached completion. The first series of steamers from these works will make its appearance this year. One of the big schemes of the Darracq-Serpollet combination was to contract, on the expiration of the present lease, for the entire Paris 'bus service, replacing the present horse service by their new vehicles. In the earlier days of French automobiling M. Serpollet was a prominent figure in speed and endurance contests. Three years in succession he won the Nice mile speed championship, and was the holder of the Rothschild Cup. He was a Chevalier of the Legion of Honour. His death at the height of his career comes as a shock to all who knew him, and robs France of one of her most brilliant engineers.

FAMOUS DRIVERS FOR EMPEROR'S CUP.

BERLIN, Feb. 3.—Preparations for the holding of the race for the Emperor's Cup over the Taunus circuit are progressing rapidly. Owing to continued bad weather no decision has been reached as to the widening of the course, the necessity for which has been mentioned in numerous announcements regarding the race. The list of drivers who will participate, so far as is known at present, is as follows: The three Mercedes cars will be handled by Camille Jenatzy, Director Willy Pöge and Otto Salzer, it being probable that Alexander Burton will be nominated as substitute. The Eisenach factory has named Robert Schmidt and Eduard Bauer as its drivers, with J. Simpson as substitute, while the Argus interests have nominated Wilhelm Flohr. The Metallurgique drivers will be F. von Reinhardt, E. Bussing and H. Wilhelm; those of the Pipe, von Hautvast, Baron de Caters and Deplus; the de Dietrich, Duray, Rougier and Gabriel, with Sorel as substitute; and the Bianchi, Tomaselli and Maserati. The single "F. L. A. G." car will be driven by G. B. Raggio, and the Lucia by Guillaume Busson; the Mors will be in charge of Gillet Hourgiere.

The Adler works have taken time by the forelock and have already sent one of their cars over the course. With the exception of the racing seats, it is their standard touring type.

PERHAPS WEIGEL RACER FOR VANDERBILT.

On board the Cunard liner arriving from Liverpool this week was Reginald Lassen, who brought with him a new 40-horsepower English automobile known as the Weigel. Mr. Lassen claims that this machine is a combination of the features of the Renault and the Mercedes. Two Weigel machines have been entered in the French Grand Prix to be run next July. One will be driven by the designer, the other by Lee-Guinness, the famous amateur driver. It is stated that a special Weigel racer will be built for the next big race in America. The Grand Prix Weigel racers, at present under construction, will have eight-cylinder engine, the same four-cylinder group used in the 40-horsepower touring machine being mounted in duplicate.

*AUTO TRAINING
for THE COURT*

WINTER TRANSPORT RIVALS

*A Peerless
WINTER TRY-OUT*

PEERLESS QUARTETTE ON WINTER TRY-OUT.

Automobiling is an all-the-year pastime these days, and in consequence there are many winter try-outs of the new models. A car that has attracted much attention at the shows is the 1907 30-35-horsepower Peerless, the designer of which is Charles Schmidt, who came to this country from France in the early days of the industry, being at that time associated with Henry Fournier in Mors interests. Subsequently Schmidt, who rode with Fournier when that driver captured the Paris-Bordeaux and Paris-Berlin races and alternated with him at the wheel in the latter event, constructed the Packard *Gray Wolf* and piloted it over the Florida course to a mark of :46 2-5. At that time this was only two-fifths of a second behind the world's

record held by a car of twice the horsepower of the *Wolf*, which, however, clipped the American straightaway mark of :51 4-5, then possessed by Fournier and a high-powered Mors. It was a case where the pupil had progressed, built and driven a car faster than the master. Some day there may be a Peerless in the Vanderbilt race, and there are those who would like to see what Schmidt can do under present conditions. His success with the 24-horsepower *Gray Wolf* brought him a plentiful supply of fame.

President L. H. Kittredge, of the Peerless Motor Car Company, occupies the seat alongside of the designer, behind him is Sales Manager W. H. Kirkpatrick, and in the other tonneau seat is E. H. Parkhurst, the vice-president and general manager.

STEERING GEAR BASIC PATENT.

Applications for patents are things that lie dormant so long that they are usually forgotten by everyone but the applicant himself. Then the patent issues and the cat is out of the bag. This is a process that has been repeated so frequently in the

DETAILS COVERED BY THE RIKER PATENT.

automobile industry that manufacturers have become familiar with it; so much so that the fact that what is claimed to be a basic patent on steering devices has just been issued to A. L. Riker will probably not occasion the surprise it otherwise might. Mr. Riker made his application for a patent on May 15, 1902, and assigned his rights to the Electric Vehicle Company, Hartford, Conn., to which company the patent issued on January 8, 1907, its number being 840,660. That there is considerable foundation for regarding it as a basic patent will be evident from the fact that its claims cover almost every form of steering mechanism now in general use.

For instance, take the first claim of the patent, which reads as follows: "The combination of a steering pillar or shaft rotatable about its axis to steer a vehicle, a block or interengaging member movable axially thereon and means for guiding said block or interengaging member and preventing rotation thereof, and steering arm or lever attached to the end of said movable block." This is amplified by the next four claims, which it will be seen cover the essentials of the steering gear as now used by practically every car built. They read as follows:

2. "The combination of a steering pillar or shaft rotatable about its axis to steer a vehicle, a block or interengaging member movable axially thereof, connections to prevent rotation thereof, and steering arm or lever attached to the end of said movable block, said lever moving in an arc, and means connecting said lever and block whereby the end of said lever is permitted to move in an arc slightly diverging from the axis of said block while the block moves directly therein."

AUTO MEETS SEVERE WEATHER CONDITIONS.

With the recent snow which has been blanketing New York City streets came the opportunity to prove the superiority of the automobile over the horse for coping with varied weather conditions. While the horses were tugging and slipping, and, in most cases, unable to drag their loads, the automobiles were in evidence and reigning supreme in all sections. None was more wideawake to prove the merits of the automobile than Harry H. Cobe, of the Cobe Automobile Company, New York agents for the Jackson car.

Mr. Cobe, with his four-cylinder 45-horsepower car, equipped with ropes, blankets and sand, drove around the city every day during the icy spell. On the rear of the car he carried a sign, "The Humane Car." With the car he helped the horses that

3. The combination of a steering pillar or shaft rotatable about its axis to steer a vehicle, a block or interengaging member movable axially thereof, a steering arm or lever attached to the end of said movable block, and means coacting with said block to prevent its rotation, interconnection mechanism between the pillar and the steering road-wheels of the vehicle, magnifying the motion transmitted, whereby a limited movement of the rotating shaft causes a sufficient deflecting movement of the road-wheels as and for the purpose described.

4. In combination with a steering pillar or shaft rotating about its axis to steer a vehicle, an interengaging member movable axially thereof, a steering arm or lever and connections between the latter and the axially-moving member, the axis of the said connection substantially intersecting the axis of the rotating shaft, the whole mechanism embodied as a unit of apparatus attachable to and detachable from said vehicle without the disconnection of the component parts.

5. The combination in a steering-pillar for a vehicle, of an independent traverse screw-block with flexible connections at one end and co-operating rotating steering-shaft and oscillating steering arm or lever pivoted to a part integral with the support for said steering-shaft pillar for the purpose described.

Other claims, the purport of which will be recognized as bearing particularly on devices in general use, are numbers 18, 19, 20, and 27, which, taken in connection with the accompanying drawings, reveal the wide scope of the patent.

"18. In steering mechanism for motor vehicles, a supporting and inclosing casing including means for attachment to the framework or body of the vehicle, said casing embodying a thrust-bearing and shaft-bearing substantially for the purpose described.

"19. In a steering mechanism for motor vehicles, an upright shaft, mechanism at the lower end of said shaft operatively connecting the same with an oscillating member projecting downwardly, a supporting and inclosing casing for the lower end of said shaft, an inlet to said casing from the upper part whereby the same can be used as and constitute an oil reservoir, substantially as and for the purpose described.

"20. In a steering gear for motor vehicles, including a rotating shaft and its operating hand wheel or lever, a rocking lever or arm and connections the deflectable road wheels, intermediate threaded connections for operating the latter by the former, said connections including a tabular casing, an interiorly-close-fitting shell with a threaded portion fixed thereto, and an engaging threaded member within the same whereby said casing, shell, and threaded member co-operate in supporting one another and in transmitting the motion from the hand-wheel to the rocking lever.

"27. In a steering gear for motor vehicles, the combination of interengaging threaded parts, a rocking lever, operative connections thereof of an inclosing and supporting casing comprising a plurality of sections or parts, said section or portions of the casing parted in a manner whereby ready removal or inspection or repair of the bearings of said mechanism is afforded."

SECTIONAL VIEW STEERING COLUMN.

happened to be in trouble—and many there were. One truck that was towed with its load aggregated a weight of about six tons. Another truck was pulled for about twenty blocks before it reached soft snow, where the horse could get a footing.

AUTO TRAINING FOR THE COURT ROOM.

No lawyer has had the strong searchlight of publicity directed at him with greater power in a long time than has Delphin M. Delmas, the advocate from the West who is in charge of the defence of Harry K. Thaw. Believing in the efficacy of plenty of fresh air, Mr. Delmas, in company with Henry McClay Pike, another lawyer of the celebrated case, has been taking a daily ride in a Franklin "air-cooler," supplied through the courtesy of Wyckoff, Church & Partridge.

TWENTY-NINE ENTRIES FOR THE GRAND PRIX

PARIS, Feb. 2.—The Grand Prix of the Automobile Club de France is certain with a total of twenty-nine machines, to furnish a good day's sport, but it will be lamentably lacking in internationality. Twenty-three of the twenty-nine are French racers, two are English, one is Italian, and three are Belgian. The complete list when Secretary Sautin closed his *dossier* last night was as follows:

1. Bayard-Clément (Albert Clément).
2. Bayard-Clément (Garcet).
3. Bayard-Clément (Gauderman).
4. Darracq (Wagner).
5. Darracq (Hanriot).
6. Darracq (Demogeot).
7. Motobloc (————).
8. Motobloc (————).
9. Motobloc (————).
10. Corre (D'Hespel).
11. Panhard & Levassor (Le Blon).
12. Panhard & Levassor (Heath).
13. Panhard & Levassor (Montsava).
14. Renault Frères (Szisz).
15. Renault Frères (Edmond).
16. Renault Frères (Richez).
17. Lorraine-Dietrich (Duray).
18. Lorraine-Dietrich (Rougier).
19. Lorraine-Dietrich (Gabriel).
20. Germain (Perpere).
21. Germain (Roch-Brault Fils).
22. Germain (Degrais).
23. Weigel (Lee-Guinness).
24. Weigel (Weigel).
25. Porthos (————).
26. Marchand (————).
27. Brasier (Bariller).
28. Brasier (Baras).
29. Brasier (Bablot).

It will be noticed that Mercedes, Fiat, Itala and Rolls-Royce are all absent from the list of engagements. The abstention of the two Italian and the leading German firm is deeply regretted here. Despite C. L. Charley's emphatic declaration of a non-racing policy, it was firmly believed that the Canstatt firm would figure in the great French race, as last year. Fiat and Itala have always displayed such a sporting spirit that their abstention comes as a disagreeable surprise. England has abandoned its boycottage of French races by the engagement of two Weigel machines, Belgium has sent three of her best cars in the Germain, and Italy has a new champion in the solitary Marchand. None of the foreign machines have previously competed in an important road

PROPOSED ROUTE NEAR DIEPPE.

race, and in view of the poor display that has always been made by newcomers in French road races, they are not looked upon as very dangerous competitors. If such an exchange were possible, there is no doubt that the officials of the A. C. F. would barter the whole group for a Mercedes, a Fiat and an Itala. A really international

race had been expected, and not even the big entrance list and the several new firms remove the feeling of disappointment. The newcomers among the French firms are Motobloc, Corre, and Porthos. Motobloc and Corre have a good reputation as builders of touring machines; Porthos, on the other hand, is practically unknown to the French public. There are a number of new drivers; Gauderman, of the Bayard-Clément team, has not previously held the steering wheel of a flyer in a first-rate contest, but he is looked upon as an equal of his companions, Albert Clément and Garcet. As a footballer and all-round athlete he has few equals. A long training at the Bayard-Clément factory has made of him a first-rate mechanic. It is not generally known that Gauderman accompanied Albert Clément, of whom he is a close friend, during his trip to America for the first Vanderbilt Cup contest.

THE EVREUX CANDIDATE.

The Panhard team has been entirely remodeled. George Heath, known here as the gentleman driver, retains his post, and is joined by free lance Le Blon and Montsava, a gentleman driver, who has not previously figured in road racing, and who hides his identity under this *nom de guerre*. The three Belgian drivers to handle the Germain machines have received a thorough training in touring contests. The most sensational entry is that of the young English millionaire brewer, Lee Guinness, as driver of a British-built Weigel racer. Lee Guinness has made himself famous as the owner and driver of the 200-horsepower record-breaking Darracq machine.

M. Brasier, who has entered three machines, says that his 1907 flyers will be very similar to those of last year. They will be rather more powerful, developing 110-horsepower, against 100 last year, will have a number of detail improvements, and will have chain drive.

No definite decision has yet been arrived at regarding a circuit, but the probabilities are that the Seine Inferieure will be selected. Only two candidates now remain out of a first list of at least a dozen, the rivals being the Eure, with Evreux as its chief town, and Seine Inferieure, with Dieppe as headquarters. Both Evreux and Dieppe have offered a subsidy of \$20,000 to the A. C. F., but the promise of the latter is regarded as more important than that of the former, the Seine Inferieure district being one which draws to it thousands of holiday makers every year. Evreux, on the other hand, has no charms beyond its good roads, and, profiting by past experience, the Club is inclined to hesitate at the offer of a big subvention from a poor district. Being on the seashore, Dieppe would receive hundreds of Englishmen for the race, and it is quite natural to expect that numbers of Parisians would choose this seaside resort for their holiday if there was the additional attraction of an automobile race. The Grand Prix must be a paying affair this year, hence the importance of the choice of a course. The total income from the Grand Prix can be estimated at not less than \$75,000. Entrance fees give \$29,000, subsidy \$20,000, and \$26,000 is a very moderate estimate for grand stands, programs, advertising, etc. Last year, with an income of about \$55,000, the A. A. A. realized a profit of \$15,000 on the Vanderbilt contest, which sum is being employed for the benefit of automobiling in general. The French club has never shown a balance and last year had a heavy loss on its race.

THE LITTLE GRAND PRIX IN JEOPARDY.

PARIS, Feb. 2.—Judging from the present conditions of the engagement list, the Sporting Commission Cup, sometimes known as Grand Prix No. 2, will not be a huge success. The race will be run either the day before or the day after the Grand Prix, and on the same course. Regulations are practically the same as for the Grand Prix, except that the fuel allowance will be reduced by one-half—3.3 gallons per 62.1 miles—and that the distance is lowered to about 310 miles. It was thought that under such regulations many firms unable to build special 140-horsepower flyers would make the few necessary alterations and compete with stock touring machines of forty or fifty-horsepower. Up to the present such has not been the case, and of the sixty to ninety machines which the committee counted as certain starters only three have put in an appearance. They are Gillet Forest, driver De la Touloubre; and two Darracq machines, with Wagner and Hanriot as pilots. As for the Grand Prix, there is no weight limit, and instead of stock touring machines stripped of all accessories and provided with more efficient carbureters, the racers will probably be featherweight freaks. Under such conditions everybody knows that the prize will go to a certain world-famed factory on the banks of the Seine. All objections would be removed by imposing a minimum weight, but if this were done now the two manufacturers already engaged would have just cause for complaint. Prompt action will have to be taken if the race is to be saved from complete failure, for the last day on which engagements for the contest will be received is Friday, February 15.

The French press and manufacturers are always unanimous on the need of a minimum weight limit.

FRENCH TOURING CONTEST IS CERTAIN.

PARIS, Feb. 3.—The Marquis de Dion's speed contest for touring automobiles has been received with enthusiasm in auto circles here. Officially the scheme is only in the proposition stage, but its acceptance by the A. C. F. is a foregone conclusion, and details of organization are being arranged. The event will consist of 1,000 miles endurance test in five or six days, and a speed test of 250 miles on a 50-miles circuit near Trouville. For the race a limited consumption of 3.7 gallons per 62.1 miles has been decided upon. A weight limit of 3,527 pounds including four passengers averaging 154 pounds each, will be imposed. Trouville will be chosen as headquarters, the tour starting and ending at this gay watering place during the first week in August. The Trouville circuit consists of 50 miles of the finest roads in France; in the opinion of many it is more suited for a speed contest than the circuits proposed for the Grand Prix. This corner of Normandy is extremely picturesque, the road surface is good, the width is never less than 32 feet, and in many places 60 feet; there are long straight stretches, switchback runs with 10 and 12 per cent. grade; not an important village on the course, and only one turn that cannot be taken at high speed. The co-operation of the press has been obtained in this competition, and every important Paris journal will give a gold medal to be encased in the gold cup offered by the Automobile Club of France. It will be noted that there is much resemblance between the Marquis de Dion's Press Cup race and the Sporting Commission Cup contest. The latter fixes the fuel allowance at 3.3 gallons per 62.1 miles, the former gives 3.7 gallons for the same distance. The eliminating tour and minimum weight limit, however, make the Trouville race impossible for lightweights.

THE COMING HERKOMER COMPETITION IN JUNE

BERLIN, Feb. 4.—Regulations for the Herkomer contest have now been made public and differ slightly from those of the previous years, inasmuch as everything has been done to strengthen the absolutely touring aspect of the competition. The contest is open to all motor vehicles of from 2.5 to 11 liters cylinder capacity privately owned by members of the foreign recognized and German clubs, each car to have at least four comfortable seats, bonnet, mud-guards, three lamps (one in rear), two brakes, exhaust and easy steps. Only petrol of a specific gravity of from 680 upwards may be used; additions of any kind are prohibited. The cars must be driven by amateurs; i.e., members of the above corporations not receiving any kind of recompense. The entry fee is \$90 per car until April 15; after this time until May 15 entries will only be accepted accompanied by double fees. The fees cover the liability, personal injuries, damages and fire insurances. The official program is as follows:

June 4—Examination of cars.

June 5—Dresden, Freiberg, Chemnitz, Zwickau, Leipzig, Naumburg, Weimar, Gotha, Eisenach, 227 miles.

June 6—Eisenach, Meiningen, Kessingen, Schweinfurt, Wuerzburg, Wertheim, Eberbach, Heidelberg, Mannheim, 209 miles.

June 7—Mannheim, Karlsruhe, Aachern, Oppenau, Kniebis, Freudenstadt, Horb, Sielz, Rottweil, Tuttlingen, Lindau, 228 miles.

June 8—Lindau, Weiler, Simmerberg, Immenstadt, Kempten, Fuessen, Weilheim, Starnberg, Forstenried, Munich, 142 miles. Speed trials in the Forstenried Park.

June 9—Exhibition of cars at Munich.

June 10—Munich, Bichel, Kochel, Kesselberg, Walchensee, Mittenwald, Partenkirchen, Oberammergau, Landsberg, Lechfeld, Augsburg, 141 miles. Hill climb on the Kesselberg road.

June 11—Augsburg, Donauwoerth, Noerdlingen, Lohr, Uffenheim, Wuerzburg, Post Rosbrunn, Marktbeidenfeld, Aschaffenburg, Hanau, Frankfurt A. M., 203 miles.

June 12—Prize distribution and banquet at Frankfurt.

At least three adult passengers, including the observer, must be on every car throughout; on the speed and hill tests there must be four, or in lieu of the fourth 70 kilos of ballast. All repairs must be made by the driver and chauffeur, or in lieu of such by a designated passenger. At the various stages the cars will be handed over to the official commissioner, who takes them in charge and only returns them to the observers 45 minutes before the start. These 45 minutes may be utilized for cleaning, oiling, lubricating, filling tanks, etc. The changing of tire covers is excepted.

Awards will be made on the following basis: The victor is the car with the least points. One point will be debited for every commenced minute of involuntary stoppage; five points will be debited for changing and repairing tires, even if done in the 45 minutes before the start. Taking in water after starting time is three points; three will also be given for any repairs which overstep the 45 minutes limit before the start. A late commencement caused by anything else is one point. No points will be given for taking in oil and gasoline at official stations or changing and repairing inner tires. The speed and hill-climb tests will be awarded according to a special table not yet published, but the cars will be debited or credited one-tenth of a point for every commenced percentage faster or slower than the normal speed fixed for each. A car with 50 points has no claim on any award for the speed trials or tests. Should more than one car have the same number of points, the hill-climb and speed trial results will be taken into consideration. Passing will be allowed except in villages and at corners; it is likewise forbidden on the Munich-Kochel stretch and from Starnberg to the speed trials start in the Forstenried Park.

Valuable prizes have been given by the Imperial and Bavarian clubs as well as the cities of Dresden, Leipsic, Munich, Mannheim, etc.

Last year the United States was represented with a Pierce Great Arrow, driven by Percy Pierce. It is hoped that American cars will line up this time also.

HOW THE NEW FORD SIX-CYLINDER, 40-HORSEPOWER RUNABOUT APPEARS ON SIDE VIEW.

FORD BRINGS OUT "SIX-FORTY" RUNABOUT.

Taking advantage of the very general demand that exists for the high-powered runabout at the present time, the makers of the Ford have decided to feature a car of this type in their line for the coming season. The chassis of the six-cylinder Ford lends itself readily to an extremely racy looking runabout body, as will be evident at a glance from the accompanying photograph of the newcomer. The details of the power plant and remaining essentials of the runabout are to be the same as the touring car, with the exception of the wheels, which are 36 inches in diameter, in place of the 34-inch wheels used on the former, and also with the exception of the mudguards, which have been designed especially to blend with the lines of the car. The wheelbase is 120 inches, and, over all, the car measures about thirteen feet.

Its every line is indicative of speed and easy riding qualities, the long bonnet, denoting the six-cylinder motor, being even more accentuated by the recessed dash forming a protective cover for the electrical equipment. A unique feature of the body design of the car is to be found in the combination of the dash and body, the under body extending forward in a straight line from the bottom of the seats, thus protecting the feet and legs of the driver without the necessity of a gate between the front seats and the dash. The seats have been placed so low that the legs of occupants will be almost horizontal. A detachable rumble seat is provided in the rear for the accommodation of a chauffeur or extra passenger, and when not in place a trunk may be carried instead, attachments and straps being provided for that purpose. The equipment throughout is the same as on the touring car, the new runabout listing at \$2,800 in complete running order and ready for the operator.

A TEXAS BUICK AUTO STAGE LINE.]

FORT WORTH, TEX., Feb. 11.—R. L. Slaughter and G. B. Garner, of Midland, have established a route for an automobile line between Big Springs and Lamesa and Lubbock, a distance of approximately 100 miles. They are representatives of the West Texas Auto Company, which owns ten Buick machines and are now making arrangements for starting the line. They will make a contract to run every day in the year except Sundays, rain or shine. In connection with the line they will establish a garage in Big Springs, and will keep a sufficient number of machines in that city to prevent an interruption of the daily service between Big Springs and Lubbock. In making this trip the line will cross five counties in which no railroads are running, being almost a pioneer line of any kind through what is almost exclusively a cattle country.

RULES FOR THE EUROPEAN INVASION.

Detailed rules have now been drawn up for the tour in Europe by American automobile manufacturers with American built machines for the Gold Cup offered by a group of prominent sportsmen. Entries for this event will be received up to May 1, and must be accompanied by at least 25 per cent. of the total fee. Particulars required are make of car, description of model, horsepower, description of body, number of seats, name of driver, passengers, etc. Cars will arrive in New York by May 30, and must be equipped with a reliable speedometer. On arriving at Havre the machines will be weighed with their full quota of passengers, baggage, etc. The frame, cylinders, driving shaft, fly wheel, gear shafts, clutch, crank shaft, radiators, steering post, wheels, axles, springs, etc., will be stamped and the existence of such stamps at the end of the run will be verified. Changes of tires and common repairs will be allowed on the road and in the garages, but penalties will be inflicted for important changes such as the following: Change of frame, cylinder, crank-shaft, front or rear axle, 300 points each; reforging any part of frame, change of driving shaft or clutch, 250 points each; reforging driving shaft, clutch, or axles, changing radiator, 200 points each; change of gear shaft or steering post, 150 points; change of fly wheel, 100 points; change of gear case, 75 points; change of wheels, springs, or crank case, 50 points each. All changes to any of the stamped parts must be reported at the close of the day's run. Any kind of tires may be used, but if spring wheels are employed they must be of American manufacture. According to the speed laws of the country, the nature of the roads and the configuration of the country traversed, a reasonable average speed will be indicated for each day's run. Speeding will not be allowed; any proved cases of excessive speed will be penalized by the jury. Hill climbing and speed tests will be held at the termination of the tour near Liverpool, and the American Gold Cup will remain in the temporary possession of the winner until won in a similar contest by another contestant in a following tour. The exact date of starting from New York has not yet been fixed.

M. MICHELIN ARRIVES IN NEW YORK.

M. Andre Michelin, director of the important French tire manufactory bearing his name, arrived in New York on board *La Savoie* last Saturday. M. Michelin, who is one of the busiest men in the French automobile world, and who has probably played a greater part in the development of the tire industry than any man living, will only stay in this country a few days to supervise Michelin American interests.

EDISON THINKS HIS PLAYTIME IS HERE.

Having fulfilled, less a decade, the Biblical restriction which says that man's life shall consist of three score years and ten, Thomas Alva Edison, the great inventor, is of the opinion that he is entitled to a vacation, and intends to take one. Sunday, February 10, was his 60th anniversary.

"I have been making experiments with electricity for 45 years," said Mr. Edison, "but during that time I have been turning them to commercial use so fast that I have never had a chance just to play with electricity for the fun of the thing, to see how much I can find out about it. It is a pleasure I have long been promising myself, and from to-morrow on I am going to give myself up to it.

"I have been deaf since I was a boy, but my hearing has been getting worse steadily, and it may not be long before it leaves me entirely, so I want to play with my phonograph while I can still hear it. The recently announced invention of submarine sound telegraphy interests me greatly, as does Dr. Cahill's telharmonium, and I may investigate them in my holiday. I am 60 years old, but only 30 in point of enthusiasm.

"My principal work in the last year has been the perfection of my storage battery. Some hundred trucks are using the earlier models in New York, but the batteries did not last as long as I thought they would. About two years was their average life. This would not solve the problem of vehicular transportation in the large cities. A battery of, say, three and a half years' life would.

"I went to work to find out what the trouble was and I found it. I shall let it go out this summer. I believe that this new form of the battery will last seven years. I have batteries now that have lasted in experimental operation between three and four years. When these are in general use in the cities the congestion will be one-quarter as great. The weight is half that of the common battery, with twice the speed.

"I am having a touring automobile built on the lines of the gasoline car, but fitted with one of my batteries. I shall tour over New Jersey in it, and then later visit New England. I can get any speed I want from it, though I shall gear it for about 30 miles an hour. With one charging the battery will take it under the most unfavorable conditions 100 miles, or, under favorable conditions, 125 miles, with four people, at a speed of 30 miles an hour.

"This will practically do away with breakdowns, and will mean that every man can be his own chauffeur. It is very simple, the principal parts being a battery and a motor. A motor needs little attention."

NORTHERN'S PORT HURON BRANCH FINISHED*

PORT HURON, MICH., Feb. 11.—The building of the Port Huron branch of the Northern Automobile Company has been completed, A. J. Smith & Sons, the contractors, having completed the structure, which contains 50,000 feet of floor space and cost \$40,000, in sixty days less than the time allotted. In addition to the main building work will begin immediately on the construction of a big warehouse in connection. As a result of the increased capacity of the plant given by the erection of the local branch in addition to the Detroit plant, the Northern Motor Car Company will make during the season of 1907 about 400 of its two-cylinder, 20-horsepower Northern touring cars.

PITTSBURG'S HILLS EASY FOR AUTOS.

PITTSBURG, Feb. 11.—Two weeks of good sleighing on deep snows have taught Pittsburgers that the automobile is a winter as well as a summer mode of conveyance. Instead of high-priced trotters and pacers hitched to sleighs that cost hundreds of dollars as a few years ago, the roads on Sewickley Heights and in the Squirrel Hill district were thickly studded with big autos. The automobiles took the snowy hills in splendid shape as soon as the snow began to pack and automobiling was pronounced "finest ever." Not only the pleasure vehicles, but the big trucks went up many notches in the estimation of the general public, for they acted much better than on the ordinary muddy or slimy streets.

The driver of a 20-horsepower three-ton Knox truck, owned by the National Lead and Oil Company, assisted in easing eight blockades in one day. The Bindley Hardware Company put on a new Logan truck just before the snows came, and it worked so well that the company has since ordered two more.

AN ATTRACTIVE HIGH SPEED CAR.

The new Rainier high-speed runabout, an illustration of which is shown, is an automobile of particularly pleasing external appearance. One of its distinctive features is a rear folding seat for two persons, which, when folded down, gives the car the appearance of a standard turtle back without a rumble seat. Wheelbase is 104 inches, track 54 inches. The engine develops 35 horsepower, the mechanical features being similar to Model C with the exception that the gasoline tank on the runabout is placed under the bonnet instead of under the front seats. The new Rainier type of springs, by which a fastening is obtained without the use of a central bolt, is employed on this model. The rear platform spring is of three-point suspension type.

THE NEW RAINIER HIGH-SPEED RUNABOUT OF 35 HORSEPOWER, WITH GASOLINE TANK UNDER THE BONNET.

TWO OPPOSED BAY STATE BILLS.

BOSTON, Feb. 11.—An example of the extremities in proposed automobile laws with which the Massachusetts legislature has to deal this winter is given in two bills recently introduced in the House of Representatives and sent to the Committee on Roads and Bridges, which has charge of all the automobile bills. One of these bills proposes that hereafter no automobiles shall be licensed which are capable of making more than twenty miles an hour, the legal speed limit. One clause reads: "This act shall not apply to any automobile or motorcycle that could have been legally operated by a resident, as owner, manufacturer or dealer, under any license granted in this commonwealth prior to the time when this act goes into effect. Any person increasing or causing to be increased the speed capacity of an automobile or motorcycle, licensed under this act, above the speed limit set by section one, or any person operating an automobile or motorcycle licensed under the provisions of this act with knowledge that the speed capacity thereof is above such limit, shall be punished by a fine of not more than one hundred dollars or by imprisonment for not more than sixty days."

The other unusual bill has directly the opposite purpose of the foregoing and apparently is intended to make possible such contests on Massachusetts highways as the Vanderbilt Cup race. It reads: "The mayor of a city or the selectmen of a town may, in their discretion, upon special occasions and subject to reasonable conditions, close the public ways and grant permits to persons to operate automobiles at any rate of speed during a specified time and upon specified portions of the public ways."

PROVISIONS OF PROPOSED PENNSY LAW.

PHILADELPHIA, Feb. 11.—Motor patrols and ambulances, and physicians answering emergency calls, are exempted from the speed provisions of a bill introduced in the State Legislature by Representative Woodward, of Allegheny County. All others must observe the following regulations: Where buildings are an average of 100 yards apart, a rate of a mile in four minutes must not be exceeded, and where corners are to be turned or curves to be negotiated, the speed must be reduced to a mile in six minutes. Where buildings are farther apart than 100 yards, the maximum speed allowable is a mile in two minutes, with a slowing down to a mile in four minutes at turns when descending steep hills and when passing other vehicles.

The proposed law further provides for a fine of \$100 or imprisonment for 30 days when an operator is convicted of driving a car while intoxicated; and that it shall be unlawful for a person under 18 years of age to receive an automobile license or drive a car. If passed, the measure will go into effect January 1, 1908.

New Jersey After Non-resident Offenders.

Local automobilists are greatly interested in a bill which has been introduced into the New Jersey Legislature authorizing the issuance of writs of attachment against non-residents of the State in suits for damages. It has been the custom for "foreign" automobilists to get outside the State limits as soon as possible after a mix-up. The proposed bill will permit the immediate issue of a writ of attachment and the holding of the car at the place where the accident or collision occurred, pending the adjustment of the damage claims.

LONG FOREIGN TOUR IN A STODDARD-DAYTON.

What the American automobile is capable of is well demonstrated by the tour of 16,000 miles made by Dr. J. W. White, of the University of Pennsylvania, in a 40-horsepower Stoddard-Dayton. Doctor and Mrs. White returned from Alexandria, Egypt, on the *Cedric*, during the past week, after an extended tour throughout the Continent in their car. Dr. White said that in all that distance they had never been delayed by a serious breakdown.

A REPORT ON AUTO INSURANCE.

ALBANY, N. Y., Feb. 11.—In his annual report to the legislature State Superintendent of Insurance Otto Kelsey thus recommends automobile insurance:

Automobile Insurance.—Inquiries received at the Department indicate a growing demand for protection of this character. It seems to be the desire of some of the insurance underwriters to have the privilege of protecting automobile owners from the following hazards:

- Personal accident to the owner;
- Personal accident to his engineer or any passenger;
- Personal accident to any other person injured by his car;
- Property damage to the car by reason of collision or other accident;
- Property damage to another car or vehicle by reason of collision with car insured.

All of these hazards properly fall under the business of casualty insurance. Personal injury to the owner may now be provided for under subdivision 2 of Section 70; to his employee or any other person under subdivision 3. The various subdivisions of this section, however, do not contemplate assuming a property damage hazard except as property may be damaged incident to burglary plate glass breakage, or by reason of steam boiler explosions. It may be desirable by express provision in the law to recognize damages to property in connection with the running of automobiles. The privilege should certainly be limited to the use of automobiles, and the property damage of the car, or caused by the car to other property, should be distinctly provided for in a new subdivision of section 70.

A NEW YORK AUTO INSURANCE MEASURE.

ALBANY, N. Y., Feb. 11.—Assemblyman Young's bill, amending the insurance law to provide for the organization of companies to insure "against loss of damage to property resulting from accident to a duly licensed automobile, and against loss or damage to property resulting from accident when caused by a duly licensed automobile," has passed the Assembly without objection. It is now in the Senate committee on insurance.

TOLL FOR AUTOS IN NEW YORK STATE?

ALBANY, N. Y., Feb. 12.—At the Monday night session of the legislature, Assemblyman G. H. Whitney, of Saratoga, introduced the following bill to make owners of motor vehicles pay toll wherever there is a toll gate. The bill reads:

An Act to regulate, fix and prescribe tolls for motor vehicles traveling upon toll roads and bridges, where such tolls are not otherwise prescribed by law.

The People of the State of New York, represented in Senate and Assembly, do enact as follows:

Section 1. Where a different rate is not otherwise prescribed or permitted by law, any person or corporation maintaining a plank road, turnpike road or bridge, and authorized, or which shall be hereafter authorized, to receive tolls for the passage of vehicles over the same, may charge and receive for each and every motor vehicle propelled by any power other than animal power, passing over the same, a toll rate not greater than the maximum rate allowed by law to be charged and received for the passage of a vehicle drawn over such road or bridge by two or more animals, provided that for such motor vehicles designed to carry only a single person the rate of toll charged or received shall not exceed the maximum rate allowed by law to be charged and received for the passage of a vehicle drawn over such road or bridge, without a load, by a single animal.

Section 2. This act shall take effect immediately.

PITTSBURG HAS A PRACTICAL AUTO SCHOOL.

PITTSBURG, Feb. 11.—A decided feature in the automobile situation in Pittsburg this year is the new Auto Transportation School, at 5906 Penn avenue, East End, one square from the "bunch." When started a few weeks ago many predicted that it would die a quick death. Instead the big building is crowded day and night with learners, both beginners and men and women who have driven their own cars for years. All sorts of information relative to the handling of automobiles and engines of all kinds is imparted and actual practice in driving a car is given the members of the big class.

[UNIVERSITY AUTOMOBILE COMPANY'S GARAGE, NEW HAVEN.

Connecticut's Center of Learning Has New Garage.

A new garage, one of the few specially designed and built for the purpose for which it is being used, has been opened at St. John and Olive streets, New Haven, Conn., by the Universal Automobile Company. The Olive street building measures 45 by 200 feet; St. John street has 35 by 100 feet. The garage is fitted throughout in first-class style, complete with machine shop, vulcanizing plant, hot water heating, ladies' room, private lockers, and has accommodation for 200 cars. In addition to holding agencies for several well-known automobiles, the company builds the Continental car in two models: a 30-horsepower shaft-driven runabout and a 40-horsepower touring car.

New Type of Garage and Salesroom at Louisville.

Easy entrance and exit is an original and valuable feature of the new automobile garage built by Longest Brothers Company, Inc., of Louisville, Ky. As will be seen from the engraving, the showroom occupies the center portion of the building, with a doorway on each side. Entering or leaving the garage, usually a matter requiring a certain amount of skill, is in this case a very simple affair, for there is no danger of suddenly finding the passage obstructed by a car coming in the opposite direction. The Longest Brothers' garage has 70 feet frontage and is 200 feet deep. The front building is used entirely as showrooms and office, behind this being the garage. On the second floor is an equally roomy repair shop.

Increased Facilities for Leading Toledo Garage.

The Rivers-Jacoby Automobile Company, of Toledo, O., has just increased its capitalization for the purpose of increasing its business. The company has been operating a garage on Monroe street, and it is the purpose to erect a large addition to its building and install a modern automobile repair shop. Those interested in the concern are A. D. Rivers, W. E. Jacoby, A. F. Nicklett, C. G. Smith and E. E. Davis.

Free Garage for a New York Theater's Patrons.

The Majestic Theater, of New York City, which is located in the heart of the automobile trade district, has made a bid for popularity by offering free garage accommodations during the continuance of the play to patrons desiring to make the trips to and from the theater in their automobiles. A neighboring garage has been engaged by the theater management to take care of the cars while the play is on.

Toronto's Big Garage in Course of Construction.

Canada will have its finest automobile garage in the new building being erected for Hyslop Brothers at the corner of Shuter

and Victoria streets, Toronto. The new structure will have three stories 100 by 100 feet, of fireproof cement, fitted with elevators and every convenience. The cost will be \$100,000.

Upper Ohio Valley Has a Fireproof Garage.

A garage to accommodate twelve large cars has just been completed in East Liverpool which will be under the direction of H. H. Knowles. It is planned to keep a complete outfit of supplies on hand continually. The garage is fireproof, the only one of its character in the upper Ohio Valley.

GLEANED AMONG THE GARAGES

The first automobile garage in Cheyenne, Wyo., has been opened by Wright & Lawson, at 1719 Capitol avenue.

There will be an automobile garage in connection with the new Harvey House, at present under construction, at Hutchinson, Kan.

A new fireproof garage will be erected shortly at First and Adams streets, Marion, Ind., to replace the one burned down recently.

Millward & Cook have succeeded the Palace Automobile and Machine Company in the garage business at 208-214 West 124th street, New York City, at Seventh avenue drive.

About March 1 the new garage of the Woodstock Auto Company, at 1943 North Woodstock street, Philadelphia, will be completed. There will be accommodation for 200 cars.

A fine, large garage is soon to be built in Waterbury, Vt., by W. F. Davis, proprietor of Waterbury Inn. The building will be completed in time for the opening of the automobile season.

A lease has been secured by the Rockford (Ill.) Engineering Company of the new Cutler building, in that city, and it will be fitted as a modern garage and be opened about May 1 for service.

The Imperial Motor Company, of Buffalo, N. Y., has filed plans in the bureau of building for the construction of a two-story brick store and garage to be erected at 1094 Main street at a cost of \$30,000.

The southeast corner of One Hundred and First street and Broadway has been leased to the Bloomfields Leasing Company, which will erect stores and offices on the Broadway front and a fireproof garage on the rest of the plot.

The proposal to have a municipal garage for the City of New York under the Brooklyn Bridge, at the Brooklyn end, has been filed for future reference. The mayor says that such a location would not be convenient for all sections of the municipality.

LOUISVILLE'S LATEST APPROVED TYPE OF GARAGE.

Pitman-Nelson Auto Company has purchased the garage at 2608 Shattuck avenue, Berkeley, Cal., to be known in future as the Shattuck Avenue Garage. Another garage belonging to the same company is located at Addison street, a little below Shattuck avenue, that city.

Plans have been prepared for a garage 52 feet by 200 feet, to be located on Jefferson avenue, between Antoine and Hastings streets, Detroit, Mich. The new concern will be known as the Fee-Vincent Electric Car Company, and will handle electric vehicles only. The Woods electric agency has been secured.

The Winton Motor Carriage Company has let the contract to Gailey & Chambers for its \$30,000 garage to be built in Beatty street, East End, Pittsburg, Pa., one square from the "Bunch." This is on a leased site adjoining the Winton garage, which was burned a few weeks ago.

Arthur Gardiner, well known in automobiling as the result of his Rambler connections, is building a new garage at Kenosha, Wis., which will be opened in the near future. Kenosha is on the direct line between Chicago and Milwaukee, and a garage in that city will be a great convenience to tourists. Mr. Gardiner will also be remembered as one of the old-time champions of cycling.

The Standard Automobile Company, of Pittsburg, Pa., has leased from Nicola & Shenk one-half of the first floor of the new Century Building, in Seventh street near Penn avenue, for a downtown garage. The building is a twelve-story reinforced concrete structure, the highest of its kind in the city. It gets one of the most central locations downtown, and the quarters will be finished and fitted up to its order. This lease is significant, as it makes five big East End firms which now have downtown garages, the others being the Banker Brothers Company, which lately leased a big room in Diamond street; the Keystone Automobile Company, which occupies a large space on the first floor of the Fulton skyscraper; the D. P. Collins Company, in Seventh avenue, and E. D. Nevin, with the Darracq agency at 507 Wood street.

MR. WINKLEY ON TRADE PUBLICATIONS.

At the monthly meeting and dinner of the New York Advertising League held at the rooms of the Aldine Association, January 29, Robert L. Winkley, manager of the department of publicity of the Pope Manufacturing Company, spoke on "The Ethics of Advertising," and said in part:

The trade paper proposition, too, has received its share of discussion. Personally, again, I am very strong in favor of a liberal use of space in these mediums. The traveling salesman and dealers throughout the country are constant readers of trade papers that draw from them an inspiration which comes in like form from no other source. Their use brings the manufacturer close to the selling end of the business and he gets the benefit of that "word of mouth" publicity—one of the most valuable kind of advertising. I don't mean by this that trade papers are lacking in those elements we look for in publications of general circulation, but I would emphasize this point as of importance in the consideration of the subject: There are four specific view points—that of the maker, the seller, the publisher and the user, and the ethics of each should be studied, determined and carefully observed. The maker who forges to the front and accomplishes something for the best interests of the industry is entitled to have the columns of the papers open to the news items in connection with his work, and I find the editors as a rule ready and willing to co-operate in spreading abroad the description of new and valuable inventions which are of interest to the public.

ACTIVITIES OF THE A. C. OF BUFFALO.

BUFFALO, Feb. 11.—Owing to much annoyance local automobilists are having from automobile thieves, the Automobile Club of Buffalo has decided to offer a reward of \$50 for the arrest and conviction of any person stealing an automobile which is the property of a member of the club.

The Automobile Club has appointed a committee of three, composed of President Seymour P. White, Treasurer John M. Satterfield and Director Charles Clifton to undertake the preliminary investigations for the proposed boulevard from Buffalo to Niagara Falls.

AN ENTHUSIASTIC AUTO FAMILY.

George J. Grossman, president of the United States Title Guaranty & Indemnity Company, No. 160 Broadway, New York City, has tendered his resignation, and in the immediate future will become identified with the automobile industry in company with his two sons, Mortimer M. and Wallace G. Grossman, to whom it is said he has given \$100,000 to carry on experimental and manufacturing work in automobiles.

"Yes, I think we are automobile cranks," says Mr. Grossman, "and I hope and believe that my boys will turn out the perfect car of the future, which will be an electric. We propose erecting a mammoth garage and experimental station at White Plains, N. Y., which will cover a city block and a half, will have the largest concrete span in the world, and I think will also be the largest garage ever built."

A TEST OF THE MIDGLEY TREAD.

Hiram Percy Maxim, chief engineer of the Electric Vehicle Company, Hartford, Conn., has just made an especially severe test of the Midgley Tread, which the Hartford Rubber Works Company has recently brought out to solve the side slip problem on their Dunlop and Clincher type tires. He drove a 24-horsepower Columbia, a touring car, carrying three people, up Church street hill, Hartford, a 22 per cent. grade, eight inches deep with snow, while the ground underneath was covered with ice from a recent thaw. This hill is so bad that it is seldom used by any form of vehicle, even in summer. Two 32x4 rear tires with the Midgley Tread was the equipment, regular smooth tires being used in front.

Not only was there no tendency to slip, but Mr. Maxim was able to stop in the middle of the hill and "pick up" again from a stand-still. He adds, "I consider this a very severe test on any kind of tire, and it shows the great advantage of a lot of little points, rather than a few large ones." As a matter of fact there are always not less than 200 separate and distinct points in contact with the road surface at one time; and in an average-size Dunlop tire with Midgley Tread there are 3,344 points which grip the ground during one revolution of a wheel.

TESTING THE MIDGLEY TREAD AT HARTFORD.

NEWS AND TRADE MISCELLANY.

Owing to its inability to have the name "Keystone" registered, the Penn Petroleum Company, of Philadelphia, has changed the name of its Keystone motor oils to Primus motor oils.

The Pope Motor Car Company, of Toledo, O., has advised the Hartford Suspension Company, of New York, that it is receiving a large number of orders for the Hartford shock absorber to be equipped on cars when shipped from the factory.

An error as to tire dimensions crept into the Morgan & Wright advertisement in the January 24 issue of THE AUTOMOBILE, making what should have been "30 x 3 1-2-inch" read "30 x 30 1-2-inch." As Mr. Hubbs, of the big Detroit company states: "We have not yet begun the manufacture of tires of this size."

The Reo Motor Car Company's Cleveland branch has been awarded a contract by the city of Cleveland for a runabout for the park engineer. This is the sixth Reo runabout now owned by the city of Cleveland, and in constant service by the municipal department heads. It is claimed that in every case the Reo company's bid was the full price of the car.

Holley Brothers Company, Detroit, Mich., the well-known carburetor manufacturing house, has closed a contract with Alexander Winton whereby it secures the exclusive right to manufacture for the general trade the new carburetor which made its appearance last fall on the Winton Model M and Type X-I-V. This carburetor has no auxiliary air inlet, and has demonstrated itself to be a highly satisfactory producer of gas.

The three-ton Reliance truck that made the recent trip from Detroit to Chicago was equipped with genuine Firestone side-wire motor tires, and much of the success of the trip, which was undoubtedly the longest officially recorded trip made by a commercial car in this country, was due to the "stick to business" qualities of the Firestones. At the finish of the journey the tires were in excellent condition, despite the rough, frozen roads and general hard usage.

The Rauch & Lang Carriage Company, of Cleveland, which for the past three years has been engaged in the manufacture of electric automobiles, has increased its capital stock from \$75,000 to \$250,000. A large addition to its manufacturing establishment will be erected, and the company hopes to complete it in time to take care of the demand next spring. C. L. F. Wieber, a prominent Cleveland merchant, has become identified with the company, and Harry N. Ravenscroft, associated with Mr. Wieber, will enter the sales department.

The Mitchell Motor Car Company, of Racine, Wis., has received a cablegram from its Paris agent, C. N. Sauerbach, urgently requesting delivery of sixty additional cars for the coming season, which is strongly indicative of the advance American machines are making abroad. M. Sauerbach's contract this year is for forty cars, and early last fall he secured an option on 200 Mitchells for 1908 delivery. The Mitchell people are making three models this year, a \$1,000 runabout, a \$2,000 touring car, and a \$2,000 truck. As soon as the frost is

out of the ground operations will be begun on further additions to the plant, which will enable an increase in the output to 2,500 cars annually.

Dr. E. G. Reinert, of Hartford, Conn., who owns a Mark XII Columbia electric runabout, was much in evidence during the recent heavy storm attending to his patients. The doctor up to the present time, according to his Veeder cyclo-meter, has driven his little electric 70,000 miles, the period of service extending back some seven years, when motor cars were few and far between. The doctor was one of the first to own a car in Hartford. He never makes use of any sort of chain grip, and has experienced but little tire trouble.

The Fellwock Automobile & Manufacturing Company has been organized in Evansville, Ind. Incorporation papers showing a capital stock of \$30,000 have been filed, and the company is ready for manufacturing. Those interested are W. E. Fellwock, president; J. F. Fellwock, vice-president, and P. B. Fellwock, secretary and treasurer. It is stated that the company will have the agency for the Maxwell, the Stoddard-Dayton and the Baker electric cars, in addition to the extensive manufacturing it will conduct. A tonneau, or surrey seat, to sell at \$50, and made to fit many of the standard runabouts, will be made. It will be furnished complete with steps, hook, rubber mat and tip, and it is asserted that it can be set on and securely fastened in thirty seconds. Turntables, tops and shields will be made. One of the principal top models is a detachable top to fit the Maxwell runabout. It is upholstered in cloth, has French bevel plates, is made from sound lumber and genuine leather. It will sell for \$200. The front and rear glasses are hinged at the top, and can be swung up at will.

NEW AGENCIES ESTABLISHED.

J. L. B. Wilhide, 2329 Madison avenue, Baltimore, has been appointed agent for the Atlas commercial cars in that city, by the Knox Motor Truck Company, of Springfield, Mass.

The Stearns car will be handled at Los Angeles, Cal., by A. H. Braley, 400 South Spring street. The good hill-climbing qualities of the Stearns have made it a popular seller on the Pacific coast.

The Winton Motor Carriage Company announces that its new branch, about to be established in Detroit, is to be in the nature of a surprise to that city of automobiles. The interests of Frank Smith, the former representative, have been purchased, and his establishment at 248 Jefferson avenue will be continued until a suitable site for the erection of a modern salesroom and garage can be found. The new branch will be under the management of Thomas W. Henderson, son of the vice-president of the company.

The Consolidated Wagon & Machine Company, of Salt Lake City, Utah, Geo. T. Odell, general manager, has taken the agency for the Knox waterless pleasure and commercial vehicles for the states of Utah and Idaho. The Myronda Motor Car Company, 1012 North Grand avenue, St. Louis, has taken the agency

for St. Louis and the adjoining counties in Illinois and Missouri; the Kentucky Automobile Company, of Louisville, Ky., for the State of Kentucky; A. A. Irion, Jr., for Waterbury, Conn., and vicinity.

Two new firms handling foreign cars have recently been added to Philadelphia's automobile colony, Louis I. Matthews and T. Hollingsworth Andrews, Jr., under the firm name of Matthews & Andrews, handling the Renault, Panhard, and Delaunay, in the Harrison building, and William E. Walter, representing the English Daimler, at 710-11 Girard building. Another foreign car to secure representation in the Quaker City during the past week was the Clément-Bayard, for which the Stehle Company, 205 North Broad street, and which also handles the York Pullman, has secured the local agency.

PERSONAL TRADE MENTION.

R. L. Kingston has just relinquished his connection with the Harburg Tire Company, of New York City. Frank G. Hill has been appointed the new sales manager.

Albert C. Galbraith has joined the selling forces of the International Rubber Company, of Milltown, N. J., and will travel in Pennsylvania, Maryland, Delaware, and Virginia.

A. S. LeVino announces his resignation as sales manager of the Ajax-Grieb Rubber Company, same to take effect this week. It is understood that Mr. LeVino is to become connected with a well-known automobile manufacturing company.

C. W. Kelsey, who has resigned as Eastern sales manager of the Maxwell-Briscoe Motor Company, states that his new connection will be announced in the near future. Mr. Kelsey recently visited the other side, and it is understood that his new position will be related to a foreign make.

C. E. Denzer, who has been for five years connected with The White Company, has been placed in charge of the White branch in Chicago, taking the place of Webb Jay, who is no longer connected with the organization. As announced some months ago, the Chicago office will be under the general supervision of C. A. Hawkins, Western sales manager of The White Company.

Recently it was erroneously stated in these columns, through information from an apparently unreliable source, that C. J. Metzger had resigned as sales manager of the Woods Motor Vehicle Company. Mr. Metzger gave public denial to the story by figuring as one of the most indefatigable workers of the Chicago show, it being said that as a result of his labors a substantial number of Woods orders had been booked.

AFTER A DEALER IN EVERY CITY.

A. H. Funke, of 83 Chambers street, New York, has been appointed sole agent for the United States for S. Smith & Son, of London, England, whose speedometer is widely and favorably known throughout Europe. Mr. Funke has a special proposition to make to the trade, and desires to hear from one good dealer in every city.

INFORMATION FOR AUTO USERS.

Useful Auto Appliances.—The Appliance Manufacturing Company, of West Jackson Boulevard, Chicago, has produced quite a number of useful fittings for the automobile. Their Amco fender is a new device, which, when attached to the automobile, effectively protects the lamps and radiator from injury arising from accidental collision with obstructions. It is substantially made of a heavy front tube, steel side rods, and

THE AMCO AUTOMOBILE FENDER.

solid brass hangers and guides and steel-coiled springs. Side blows, much more frequent in dense traffic than end-on blows, are equally well provided against by this apparatus. The fender is adjustable to fit any automobile. It is made in two finishes, the standard type, with black enameled front bar, polished brass tips, brackets and guides, listing at \$20; and a special finish, smooth, ready for painters, with brass parts polished, selling at \$18. The Amco extra tire holders are made in various symmetrical designs for holding either one or two tires. Lightness and strength have been combined, and security is assured by a Yale lock. There are no set-screw heads to tear

IMPROVED AMCO TIRE HOLDERS.

clothing, and a valuable feature of the holders is the ease with which they can be removed when not in use, without the aid of any tool. The Amco long-distance horn is another new appliance. It is blown from the exhaust of the engine, has a revolving reed, gives an unmistakable warning note and will not clog or get out of order.

Luverne Solid Tire Wheels.—The usual procedure when an automobile owner decides to change from pneumatic to solid tires is to fit the solid tires on his old rims so as to save the trouble and expense of making any change on same. When he gets these solid tires on his rims they will be so fixed that he cannot use his pneumatic tires any more, and his solid tires are considerably less in diameter than the pneumatics were. Be-

ing small they ride hard, and, in addition, are more apt to skid. The method of the Luverne Automobile Company is to furnish a new set of wheels with Firestone side wire, solid tires attached. These wheels are made to fit customers' hubs, and as all artillery wheels are so made that the hubs can be taken out without damaging the wheels, it is possible to keep the old wheels, with pneumatic tires, in reserve to be used again if desired. The solid-tired wheels are made somewhat larger in diameter than the pneumatic-tired wheels. Thus 30 inches outside diameter would be increased to 31 or 32 inches, it being important with solid-tire wheels to use as large diameters as possible up to a certain point.

Grinding and Buffing Motors.—The Lamb Electric Company, of 32 Canal street, Grand Rapids, Mich., has placed on the market a direct current grinding and buffing motor for jewelers, silversmiths and metal workers. Some of its

DIRECT-CURRENT BUFFING MACHINE.

features are great torque or pulling power, smooth running obtained through perfect balancing and extra long and large bearings, brushes are of carbon and easily accessible, commutators are of copper thoroughly insulated with mica, armatures are the slotted type, with the conductors carefully embedded in the slots, field magnets are one-piece castings of high permeability, and field and armature coils are wound with the best magnet wire. The motors vary in size from 1-4 to 2-horsepower, their price being from \$50 to \$130. With each motor is included a snap switch, 10 feet flexible cord and an attachment plug with the 1-4-horsepower size. Starting boxes are furnished with the larger sizes, instead of snap switch cord and plug. Emery wheel can also be added as an extra.

Weeber Valve Tool.—As its name implies, the Weeber Valve tool, manufactured by the C. F. Weeber Manufacturing Company, Albany, N. Y., is designed to

TOOL FOR VALVE REMOVAL.

quickly remove valves from gasoline motors. In addition it is a very handy tool to aid in removing and placing tires and side rings, or compressing things where clamps are needed, thereby making it a very useful instrument for the auto kit or shop use. The selling price is \$2.50.

A Self-Cleaning Plug.—The entirely original feature of the Holsten spark plug, manufactured by the Triumph Engineering Company, 226-230 Lafayette street, New York, is that it is self-clean-

SECTIONAL VIEW OF HOLSTEN PLUG.

ing. The central pin or electrode is surrounded by a composition inside of the mica washers, giving superior insulation. The formation of any carbon on the sparking points is prevented by the valve movement of the insulating section. This movement is very slight, less than 1-32 of an inch, but sufficient to accomplish its purpose and keep the sparking points clean. It combines in a measure the advantages of the make-and-break system with the jump spark. At the time of the explosion the valve is tight, but it drops back on the down stroke of the piston far enough to make the electrodes touch, and keep them clean. As a proof of their confidence in the value of the plug the manufacturers give a five-years' guarantee.

Radium Polish is one of those little things necessary to the chauffeur who takes any interest in the condition of his brass work. It will produce a quick, easy polish on all kinds of metal, and is guaranteed not to scratch the finest surface. It is handily put up in the form of a round bar and does not spill or waste in use. Retail selling price is 10 cents, with a special discount to dealers and jobbers.

Aluminum Bodies.—As an example of the various types of aluminum bodies produced by them, J. M. Quinby & Company, of Newark, N. J., have produced an illustrated catalogue showing limousines, coupés, landaulets, double phaeton and runabout bodies, in their finished colorings. The firm announces that it has completed the extensive additions to its plant, and is now installing a complete repair shop for overhauling high-grade chassis. A number of machines are carried in stock, including Renault, F. I. A. T., Panhard, and Simplex, fitted with Quinby aluminum bodies.

THE AUTOMOBILE

THE dream of all automobilists is to make the tour of the Loire Chateaux. The Loire country is the touring ground *par excellence* for automobilists, and the wealth of romance and history still radiates from its old chateaux with a medieval splendor that is yet undimmed by the rush of twentieth century progress, and will remain so for many a day

The automobilist from over-seas, en tour in France, is still—for some inexplicable reason—drawn Parisward, there to fool away a good bit of time which might be better spent in pleasurable and profitable travel. It may be that the tourist thinks his automobile needs a course of Paris doctoring—or his chauffeur does his best to make him think so—but there are far better *mécaniciens* in the great provincial towns like Rouen, Evreux or Chartres, and they are not nearly so likely to put sand in your gear-box or detach your ground wire, and spend two days hunting for the connection at your expense. Besides this, their prices are cheaper for what is really required, and your chauffeur has no likely chance of being able to pull in a rake-off as is his due by the unwritten law of the Avenue de la Grande Armée. As for yourself, you will be saved the *ennui* of hanging around Paris in the interval, and eating the same sort of table d'hôte dinners that you would in New York, London or Vienna, killing time at Henry's with cocktails at a franc apiece, or indulging in similar pastimes.

Avoid Paris, then, en route from your port of debarkation, if at all possible, and leave your automobile at Evreux or Chartres and go into town by train, if you must, in eighty minutes and avoid the deadly kilometers of Louis Quatorze *pavé* which surround Paris in every direction. Garage accommodation is cheap in the provinces; most likely you will pay but a franc a day until you come back and take to the road again. There is but one decent route in and out of Paris in any direction, and the writer in half a dozen years has never found it but once; for this reason he can give no directions which will prove definitely satisfactory except to avoid Paris altogether.

When the Autoist Arrives in France.

One disembarks his machine at Cherbourg or Le Havre, most likely, unless by chance he has been touring in England, when perhaps, he will arrive in France via Dieppe, which to all intents and purposes is practically the same thing so far as the present

outline itinerary is concerned. If he enters via old Boulogne-sur-Mer he must still skirt Paris to the west in order to most comfortably arrive in Touraine. In any case the route to Touraine and the chateaux country is easily traced to avoid Paris, and, indeed, is much shorter than if one doubles in and out of the capital.

From Le Havre or Dieppe, via Rouen to Chartres, or if one is a pusher, to Orleans is about all one will want to tackle in a day; in fact, it is a good deal more than will prob-

ably be accomplished the first day, in spite of the fact that the distance is only about two hundred kilometers in either case, say a hundred and twenty-five miles.

You Must First Get "Les Papiers."

If you are a stranger-automobilist in France you will have to waste half a day, or perhaps more, of valuable time in Rouen fixing up your *Certificat de Capacité* and your *Récépissé de Déclaration*, without which you may not run an automobile on the roads of France—at least so reads the law. There are many who ignore this and do actually tour France without *les papiers*, but a devoted gendarme will sooner or later catch them up and then there will be something to pay, and as like as not the auto itself will be impounded, awaiting for the law machinery to revolve. The formalities cost nothing, and it will be much better business to attend to the matter at once.

Leaving Rouen via Evreux or Vernon, one gets main roads only all the way to Touraine. By the latter route one descends the famous Côte de Gaillon just before reaching Vernon. It is

nothing so terrible as a hill; it only averages 10 per cent. grade; but it gives a straightway hill-climb for a kilometer with no turns or bends, and stopping off if you a hill-climbing contest.

Dreux, a hundred kilometers from Rouen, is a good place to take your déjeuner (Hotel de France), and you may buy *essence* and *huile* (gasoline and oil), at the hotel before you leave, at the same price you would pay for it in the town.

Chartres for the night, or for déjeuner or dinner for that matter, is a very good thing indeed; incidentally you may see the finest and rarest thirteenth-century colored glass extant, and the most graceful and ornate church-spire in the world at the cathedral. To be well and satisfactorily cared for at Chartres one must stop at the Hotel Duc de Chartres. It is nothing luxurious, and is very homely, but the food is excellently well cooked and served, which is more than it is at the Grand Monarque on the other side of the Grand Place, though the latter establishment has more up-to-date garage accommodations. *Verb. Sap.*: Send your chauffeur and your automobile to the Grand Monarque, even if it is the "swell" hotel of the place, and sit tight yourself at the Duc de Chartres—the hotel with the great white automobile hanging out over its door.

If You Come from Paris.

Coming out from Paris—if you insist on taking your automobile there—the best entrée to the Loire region is via Versailles, Rambouillet and Chartres. This is a much better road, and much more interesting to cover, than the "Route d'Orleans" direct, and it is only a trifle longer. After Chartres the great plain of La Beauce is crossed. This is the granary of France, and, if American automobiles are not yet seen in these parts in great numbers, American agricultural machines of every kind are; they are everywhere.

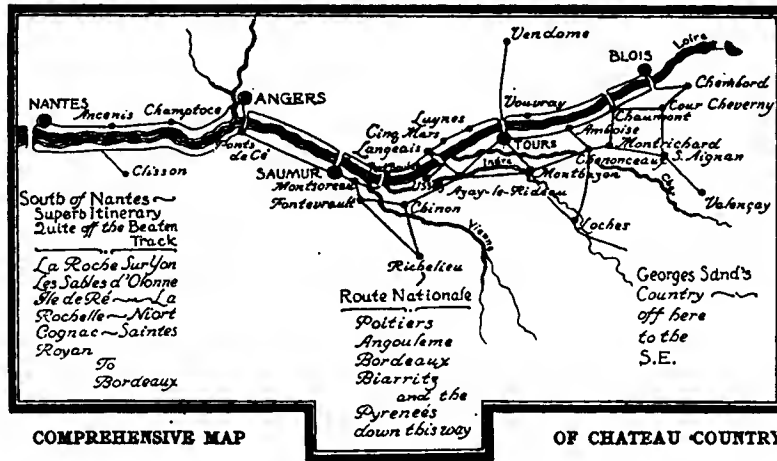

To Orleans direct from Chartres is but 78 kilometers—via Artenay, and to Blois—via Bonneval (where it is market-day three days a week: 'Warc loose chickens, ducks and sheep), and Chateaudun (where there are a lot of vile cobble-stoned streets), is something like 140 kilometers, a little short of a hundred miles.

Orleans Uninteresting Despite Jeanne d'Arc.

One ought to go to Orleans; at least one will want to go there; but without prejudice, it's the most uninteresting city of its class in all the wide land of France. It has some "sights," to be sure; a great cathedral, the storied memories of Jeanne d'Arc and some modern and not very good monuments to "The Maid," the house once habited by Agnes Sorel, and a blending of old and new that is astonishing if distressing.

The hotels of Orleans are good. The Hotel Moderne is very modern, with *art nouveau* swirls and blobs over everything from the menu-cards to the chair-backs, while the proud old Hotel St. Aignan is trying hard to keep pace with its younger rival. Accommodation for man and his modern beast—the automobile—are very good at either, and prices are about the same, say twelve francs a day for everything.

One advantage of striking in on the Loire at Orleans is in being able to follow down the right bank to Blois, and the passing through

COMPREHENSIVE MAP

OF CHATEAU COUNTRY

and stopping off if you will at one or more of those sleepy old-world towns of the Orléanais, such as St. Ay, Cléry, and Beaugency. You really should stop at Beaugency to get a nearby view of the old donjon where Francois Villon, a vagabond traveler himself, though he was a criminal, was imprisoned by the Bishops of Orleans. It was here the writer got a marvelous déjeuner one dripping wet day when his

machine positively refused to go any farther (water in the carburetor was the cause), and he confidently recommends Beaugency's Hotel de l'Ecu de Bretagne to any who want to get next to the soil. It cost a half a dollar *tout compris*, and was cheap at the price, with wine thrown in of a brand which would sell for a dollar a bottle on Broadway. This is one of the real country hotels where wine comes as a matter of course, as much as you like to drink—*à discretion* is the way the Frenchman puts it, but no one ever heard of a French country boniface cutting off his guests' wine supply, even if he had started on his third bottle.

Meung-sur-Loire follows close. It was here that Dumas laid the opening lines of his D'Artagnan romances—at the Franc-Meurier, but there is no such named inn there to-day.

Blois Can Be Seen Ten Kilometers Away.

As one draws up on Blois he sees, for ten kilometers away at least, the lone tower of its cathedral rising high above the surrounding plain. Blois is the first of the chateau towns, and is itself a great, big, overgrown burg, which, on market-day, is as redolent of butter and eggs and hens and chickens as a town of 1,500 inhabitants far from a great city.

One should make Blois his headquarters for a day or two, or even three. First there is the great state chateau of the Counts of Blois, of François Premier, of Louis XIII, and of Gaston of Orleans, whose artistic taste—or that of his advisors—fell far below that of his predecessors. The chateau is magnificent, and its legend and history, as purveyed by the guide-books, is most complete.

Chateaux Reached from Blois.

After "doing" the Chateau de Blois there is the great, bare, pompous Chambord, a dozen or fifteen kilometers only away across the sandy Sologne plain. It is quite the most surprising, and, in some ways, the most splendid of all the Loire chateaux, and all this in spite of the fact that it has been denuded to the mere skeleton and has no fittings or furnishings, depending entirely upon its architectural graces for its charm.

Still, across the sandy Sologne, where Francois and the court once hunted deer, and which now grows a wine-crop which cultivators did not believe possible in the olden days, is Cheverny, Cour-Cheverny, and Beauregard, and still within a short radius Chaumont on the Loire, one time the property of that family of French emigrés who gave the names of Chaumont and Leroy to two up-State New York towns.

A round of 50 kilometers will do all of these and bring one back again to Blois in time for dinner. The chateaux at Blois and Chambord are open every day, but those latterly mentioned may be visited only on special occasions, or in the

absence of the families now living in them. This is the case at Chaumont, for instance, which may only be viewed on Thursdays. One should make inquiries at the hotel at Blois as the opening frequently change.

The Hotel d'Angleterre et Chambord, at Blois, is a most excellent establishment of its kind. It loses somewhat the character of the *pays* in that it is so well-appointed in many little ways that the modern traveler appreciates, but all the same it is a very satisfactory hotel, indeed, and its graveled and covered courtyard and the amiability of its host and hostess make it an ideal automobilists' hotel. It has, moreover, quite the best situation in Blois, and you may dine, if you like, on the terrace overlooking the river, quite in spirit with the whole character of this soft, pleasant land. There is to be found a "tire stock" at Blois, and the *mécaniciens*, while not possessors of imposing establishments, are quite equal to the usual needed repairs.

Amboise Best Remembered of All Chateaux.

On toward Touraine from Blois, having previously visited Chaumont, one does the 37 kilometers of straightaway road to Amboise in almost no time at all. The road is absolutely flat, and runs close beside the Loire, which one crosses at Pocé to arrive at Amboise.

Amboise will be perhaps the best remembered of all the chateaux of the Loire. You may not "kodak" it, at least not inside the walls, without written permission from the Duc de Parma, to whom it belongs. Remember this and not attempt to do so, or you will be handed over to a *gendarme*, who will make you open your camera and destroy your films in his presence.

The hotel accommodation of Amboise is wholly unworthy. The Lion d'Or, a pretentious establishment on the quai, directly beneath the battlemented walls of the chateau from whence one day hung the murdered Huguenots in chains, is very far from being an efficient establishment. It doesn't even fill the bill as well as it might be made to do, and this of itself is unpardonable in the conduct of a French hotel. The visiting automobilist will do well to leave his machine at the quaside garage, even though it costs him a franc, and not attempt to get even his *déjeuner* at Amboise. If he must eat let him hunt up some little countryman's inn—there are one or two in the town nearby—and thus not pour profit into the coffers of a landlord who hasn't yet risen to the art of catering to an automobile clientele as well as he might or ought.

By the River Road to Delightful Tours.

From Amboise one may go direct to Tours by the river road or mount through the *Fôret d'Amboise*, the venue of the royal stag and wild-boar hunts of the days of François Premier and Henri II, and so to Chenonceaux in the valley of the Cher. The former program is preferable, for the Hotel du Bon Laboureur at Chenonceaux is nothing great, being simply a country-town hotel, which has lost its head over the influx of tourists, and grown decidedly commonplace in its appointments and its cooking. It's a good enough place to lunch, for there is nothing unwholesome about it, and one must come to Chenonceaux for lunch, as the chateau may only be visited between two and four in the afternoon, and not every day at that. Inquire as to this at Tours.

Tours is delightful, though it hasn't a chateau within its boundaries: Plessis-les-Tours, on the outskirts, is to-day a mere fragment, though it was once the favorite residence of Louis XI. One has to get his chief amusement out of Tours from its cathedral of St. Gatien, which Charles IX called "a bejeweled frontispiece of architecture," and the remains of the old abbey churches of St. Martin and St. Gregory. There is the birthplace of Balzac somewhere on the Rue Nationale, if one can only find it out and would worship at a literary shrine of the first rank. It will take some hunting up, as not every one in Tours knows of it, and there are not even picture-post cards of it on sale. Besides this, Tours has a magnificent

RUE JEANNE D'ARC IN ORLEANS, ONLY PASSABLY INTERESTING.

modern Hotel de Ville, quite the most splendid example of modern French Renaissance architecture extant, and there is a railway station which is a model in its appointments and services. The streets, cafés and hotels of Tours are as gorgeous as those of Paris, but are by no means slavish imitations thereof. Tours is still the delightful provincial capital of old Touraine.

As for hotels, one can hardly go wrong in Tours. There is the splendid Hotel de l'Univers, where one houses his automobile in a palatial garage, and takes his ease at dinner in full dress—if that really is taking one's ease—and then there is the little *commis-voyageur* Hotel du Croissant, in the Rue Gambetta back of the postoffice, where one gets the real thing, and as bountiful and excellent repasts as can be found throughout this land of plenty and good things to eat. It is more democratic than the Hotel de l'Univers, but the eating has decidedly more of character to it, and is a good deal better as to its cooking. The praises of the former establishment have been sung by writers of all classes of ability, and all grades of judgment, from Henry James downward, but the Hotel du Croissant is evidently a discovery of the author of these lines, as he has never met anyone in a dozen years of French travel who ever heard of it, much less having stayed there. Anything you want in the auto line is to be had at Tours in any one of the garages.

One Can Pass the Night at Loches.

If one comes out from Tours to Chenonceaux following the road by the bank of the Cher via Bléré, he must climb up to the plateau between Chenonceaux and Loches, and, crossing the

BLOIS' CHATEAU IS RICH IN HISTORY AND LEGEND.

Fôret de Loches, descend abruptly into the latter. One may pass the night at Loches readily and comfortably enough, having easily made the run (only 30 kilometers), after having viewed the splendors of Chenonceaux in the afternoon, for there is remarkably good accommodation to be had at the bannally named Hotel de la Promenade. This hotel is *bon marché*, but its déjeuner would be a marvel of bountifulness and excellence at any price. The déjeuner and dinner at this commercial-traveler sort of an hotel is a very satisfying meal indeed—the French *commis-voyageur* usually stokes heavily, though he demands that it shall be a prime quality of *nourriture*. There is another hotel at Loches—the Hotel de France—but it is not so good, and the patron's attempts at speaking English are painful and ludicrous, besides which you pay 50 centimes or a franc more for everything because of this attraction (sic).

The sights of Loches and its immediate environs are good for half a day. There is the exceedingly spectacular Renaissance chateau, the old, medieval donjon—a relic of an earlier chateau—which contains the iron cage invented by the Cardinal Balu for violent prisoners of State, and of which curiously enough he was himself the first occupant. Then there is the great

Chinon is a genuine, self-sufficient little provincial French town, whose inhabitants care not what is happening in Paris or elsewhere, and are only interested in the price of the wine crop or of this season's dried prunes. It has the relics of three non-contemporary medieval chateaux sitting proudly on a colline overlooking the town, and, besides, it has as quaint an array of old stone and timber house-fronts, coming down from medieval times, as one will see in all France. It is, moreover, the reputed birthplace of that Gargantuan eater, litterateur and wit, François Rebelais, but no one knows enough about the fact to be able to point out the house in which he was born. The Hotel de France at Chinon is about the best country hotel of its class in these parts. It is strictly *bourgeois*; the patron himself cooks the dinner and receives you and your automobile with open arms and speeds you with regret, leaving meanwhile a half a dozen fussy and fat *commis-voyageurs* complaining because their next course is not more promptly served.

A Forest Road to Azay-le-Rideau.

If one has followed the exact outline of this itinerary up to now on his automobile he must retrace his steps and traverse the

HOTEL DU CROISSANT, TOURS.

HOTEL D'ANGLETERRE, BLOIS.

IN AND OUT OF SOME LOIRE HOTELS.

barbican gateway—a veritable stage-accessory—and the bizarre Eglise de St. Ours—one of the most fantastically built churches in all France, and dating from the twelfth century, at least. The history of the connection of Agnes Sorel with this fine old church will make interesting reading for any who care for French romance. Nearby are the chateaux of Beaulieu and Montresor. In the former lived for a time the *gentil Agnès*, the beloved of Charles IX, and François Premier alike. François finally came to believe she was fickle, and the *gentil Agnès* dropped out of history, not being able to live down some satirical verses the art-loving monarch penned about her.

Delightful Run to Chinon.

It is a delightful cross-country ride of seventy-five or eighty kilometers to Chinon on the Vienne, mostly by "Routes Departementales," which, if not of the importance, generally speaking, of the "Routes Nationales," are nearly as good as to surface and upkeep. Nothing is to be dreaded on any of the five chief classes of roadways in France, save in times of very severe rains, and then roads are bad everywhere. Everywhere in Touraine the roads are astonishingly good, indeed, they are probably the best, take them all in all, in France, and there are no hills except as one mounts up out of one river valley and drops down into another.

Fôret de Chinon to Azay-le-Rideau, twenty-two kilometers. The road rises out of Chinon like the side of a house, and in a moment one is in the midst of the forest, where rabbits continually scurry across the road and a deer or a *sanglier* is apt to cross one's path at any time. It's a genuine bit of unspoiled wild-wood such as abounds only in France; that is, with perfect roads traversing them in every direction.

Chicogean Wanted to Remove This Chateaux.

Azay-le-Rideau has been called "the finest flower of the French Renaissance." With the exception of Langeais, it is quite the most livable-looking of all the Loire chateaux. In spite of this its owners have come into hard lines and the property, within a year, has been thrown upon the market. An American had all but pounced upon it and had proposed to tear it down stone by stone and erect it again on the shores of Lake Michigan, but the French Government stepped in and said nay, supplied the money for the purchase and made of it forthwith a "*monument historique*," the property of the State. Good work! The French nation should be deeply grateful.

Don't eat or sleep at Azay-le-Rideau if you can help it, but go on to Langeais, only ten kilometers away—it's astonishing how short the distances are between these great architectural treasures of Touraine.

Langeais' Fine Residential Chateau.

Langeais and its chateau are remarkable. You *déjeuner très bien* at the Lion d'Or, and it is but the proverbial stone's throw to the portcullis of the chateau. You pay a franc to a neat, white-coiffed *bonne* (you will see all through the Loire country the most remarkable succession of *coiffes* in France, with perhaps the exception of Brittany), and a dress-suited valet will take you in tow and show you the round of all the chief apartments of this fine residential chateau of to-day, even though in medieval times it was a fortress-chateau, a fact you will well realize when you first enter the portcullis gateway and afterwards make the tour of the crenelated battlements, through the holes in the floor of the outer gallery of which they used to pour boiling lead and red-hot coals on the heads of the besiegers.

The family of the present proprietor of the Chateau de Langeais graciously go into hiding every afternoon and let the public stroll about their living rooms, which are all furnished as completely as may be possible after a period contemporary with the romantic life of the chateau of other days. The good taste and judgment of this chatelain of Langeais might well be imitated by men of affairs elsewhere, for he is a busy man who

soreau, sitting right on the river's bank. Its situation is good and bad, from opposite points of view, but it is an imposing bit of architecture nevertheless. History has much to say about it and its inhabitants, and Dumas in "La Dame de Montsoreau" has embroidered them with fiction.

Lieut. Lahm Is In Attendance at Saumur.

Saumur, its chateau, its hotel de ville, its Colline des Moulins, its Hotel Budan, and its vin blanc de Saumur, sets itself out large on the horizon of Loire attractions. The traveler must hunt all these things out for himself on arriving, but on no account must he neglect the Hotel Budan, right on the quai at the end of the *pont*. It comes desperately near to being the best hotel between Paris and Bordeaux. It has an excellent garage, and its sleeping rooms are palatial, if just the least bit old-fashioned. Its table and its wine cellar are irreproachable, and its patron and his wife are of a class seldom met with among the hotelkeepers of any land. What more would one want to find?

Saumur is a genuine and thorough good thing, though its chateau, as a sight or an architectural masterpiece, is in quite another class from those flowery examples higher up in the

CHENONCEAUX.

LOCHES.

CHAMBORD.

THREE OF THE PICTURESQUE CASTLES OF THE LOIRE.

gains his livelihood in "*les affaires*" in Paris, like any hustler in Chicago or New York.

Back to Tours by River Road.

Following the river road back to Tours for twenty-four kilometers one passes the ruined castle of Richelieu's rival, Cinq-Mars, the perfidious Monsieur le Grand of the days of Louis XIII. Just beyond Cinq-Mars is the Chateau de Luynes, with a wonderful situation on a colline overlooking the river. It is a most taking outline of a chateau, with towers and turrets just where they ought to be to fill one's preconceived ideas, and the graceful Renaissance decorations of its courtyard are remarked as among the best of their epoch. This is as far as one's knowledge of the Chateau de Luynes goes.

It is forty-odd kilometers from Langeais to Saumur, where the imitation champagne comes from that is better to drink than real champagne—it is less heady and less expensive, two much-to-be-appreciated qualifications. En route one should cross the Loire again at Port Boulet, twenty-two kilometers from Tours, and follow the road by the left bank. It is but a short detour to Fontevault, where a quartette of Plantagenet royalties are buried, much to England's chagrin. It is a shrine to be visited by all who are in the neighborhood.

Back to the Loire again, one passes the Chateau de Mont-

Loire valley. What it lacks in these respects it more than makes up in character. It is a thing to see. The great government cavalry school at Saumur will interest Americans from the fact that Lieut. Lahm is in attendance there, he who won the Gordon Bennett cup in the balloon race of last year.

On the Way to Angers.

From Saumur to Angers, by either bank of the Loire, is fifty kilometers or a little more. By either route it is a delightful road, the whole character of the country changing with each kilometer. Near Angers the roads assume a dusky hue, but it is not caused by "oil," "tarmac," or "westrumite"; it is simply a surface of pounded slate, one of the chief products of the neighborhood, and a mighty good road surface it is.

Angers' marvels are many. It has a cathedral which bridges the gulf between Romanesque and Gothic architecture in such a remarkable and distinct fashion that it gave birth to a new style of building known as Angevin. The castle of Angers, built with seventeen black-banded towers along its ramparts, each with alternate layers of slate and grey-brown stone, is the most marvelously impressive chateau-fortress on the Loire. Shakespeare's King John called the city "Black Angers."

Angers, in the Cheval Blanc, a hostelry which has come down in one form or another from the fifteenth century, has perhaps

the best and most nearly perfectly appointed provincial hotel in France. It is not cheap, but it is good—very, very good. It is not modern, but it is more nearly up-to-date than many other establishments with greater claims.

One may dine in a delightfully arranged *salle à manger* at the Cheval Blanc or in the glass-covered courtyard, as he pleases, and his automobile will rest luxuriously meanwhile in a second covered courtyard to the rear. Beyond this, the Cheval Blanc at Angers and its fussy old patron with the weird cravat and the smooth-shuffling, antique garçons form an indescribable combination with which one must become personally acquainted in order to fully appreciate.

Innumerable Vineyards on River Banks.

Below Angers, on both banks, are innumerable vineyards and "*chateaux de commerce*," which furnish the wine-drinking public with the best of the Loire *crus*. On the right bank is Cham-tocé, with an old, ruined fortified chateau rising above the main street in real robber baron fashion. Varades is the next town of note, though there is nothing for the automobilist to remark until he runs into Ançenis. Here there is another old ruined chateau, and a great wire-rope bridge across the Loire, on which is a huge black-and-white scale which marks the rise and fall of the Loire flood, for in spite of the fact that the river bed is half bare most of the time, it can rise to an inordinate height, and then a warning is needed, that the lowland population below Ançenis may make such preparation as may be possible, that they may not be swept away.

Next to the Good Things of the Region.

At Ançenis at the Hotel des Voyageurs, one may *déjeuner* very well indeed on the local dishes, the genuine *plats du jour* of the country, which after all is what one comes to a new country for, or ought to be. It is better so than to be fed imitation Parisian repasts or worse canned stuff of a doubtful quality, and whether one is an automobilist or a "mere tourist" he likes to get next to the good things of the particular region he is traveling through for the moment—Bourgogne for snails, Normandy for ducks and Touraine for wine, *rillettes*, and prunes.

Ançenis is printed in large letters on the maps, but it has only 3,000 inhabitants, and there is not much doing in the way of automobile repairs should one happen to want them.

On the road again for Nantes one passes Oudon and remarks a spectacular-looking towered and turreted chateau, very stagey and possessed of nothing of interest as to its history except that it was erected as a *passé temps* of some *nouveau riche* with more money than artistic sense.

Nantes Is an Overgrown Provincial City.

The road into Nantes, though it be a great "Route Nationale," is by a series of switchback hills, which, if nothing terrifying, are at least annoying by their frequency. One is continually rushing down one slope and hoping that he will be able to climb the next on top speed.

Nantes is a great, big, overgrown provincial metropolis. It is a seaport of rank; has factories and machine shops and great wide streets and boulevards—and again others not so wide, which are so frightfully encumbered with tram lines, railway tracks and what-not that they are very difficult for automobile navigation. All the same Nantes should not be omitted from any Loire itinerary. The cathedral of St. Pierre and the celebrated sculptured tomb of François, the second Duc de Bretagne, are themselves worth the journey thither, and there is the fortress-chateau enclosing the Logis de la Duchesse Anne, which is a remarkably beautiful Renaissance work, if not very stupendous.

Delightful Old-World Towns Near Nantes.

Within a very short radius of Nantes are a fringe of delightful old-world towns, little or not at all known to the casual traveler. There is a novelty and quaintness about Cholet and Clisson and Geurande—with its ramparts and old gates—and

the curious salt manufacturing town of Bourg de Batz, to say nothing of the great seaport of St. Nazaire, and Nantes' watering place, Pornic, which will give a new chapter of emotions to the heart of the traveler already jaded with a round of big towns and conventional resorts.

The hotels of Nantes are "so-so." The Hotel de France, the premier establishment, so called, has been abominably transformed within a few months until it is not the ghost of its former self, but simply a fatuous pseudo-de-luxe hostelry which has no excuse for being at all. If you are an automobilist you are immediately shot into a room for which the price is five times its worth—this before you have time to explain that you are not a millionaire—all automobilists look alike in cap, goggles, and waterproof. Then there is the restaurant, especially designed to catch automobilists, too, with a gold-laced jackey bowing and scraping before the door. It's simply awful, and with all this you have to house your machine in a dark, stuffy little hole of a garage in which it is impossible to turn it around.

The best hotels in Nantes for the automobilist are the Hotel de Bretagne and the Hotel du Commerce et des Colonies.

No Finer Touring Ground in the World.

The itinerary herein outlined does not comprehend all of the roads to and from the chateaux of Touraine and the Loire country, no more than it epitomizes all the sights and scenes and all the delights of travel in this soft land of which Dante wrote: *Terra molle e dolce e diletta*. There is no finer touring ground in all the world, and its "sights" are more numerous and more enthrancing than any other group within a similar radius of the earth's surface.

There are four books which will smooth anyone's way through the highways and byways of this delightful land—the "Guide-Michelin, Joanne's "La Loire," "The Chateaux of Old Touraine and the Loire Country," by the author of these lines, and James' "Little Tour in France." The two first-named are indispensable; no other guides are of a whit the value of these to the automobile tourist in the chateau country.

A thousand kilometers in and out will cover the itinerary. It can be done—in part—in a week, but a fortnight or three weeks in this land of splendor and plenty will be well spent. To this all who have made the tour will agree.

NORMANDY COURSE CHOSEN FOR GRAND PRIX

PARIS, Feb. 13.—After a long process of elimination, the Seine Inferieure has been chosen as the scene of this year's race. For the last month members of the Sporting Commission have been visiting proposed districts, each member being allotted a course. The various reports were compared and a certain number chosen to be visited by the full committee. For some time the Seine Inferieure and the Eure were close competitors. Finally the former won, not so much on road merit, for it is admitted that a dozen courses could be found in France equal to this, but because it offers a subvention of \$20,000, is conveniently situated on the coast, has a good headquarters in the town of Dieppe, and is likely to attract a large number of French and foreign spectators on account of its geographical position. This quarter of Normandy is the most fashionable and populous holiday district in France, and Victor Breyer, who is acting as general manager for the club, should have no difficulty in handing a big balance over as net profits. English and American visitors to the race will find the course advantageously placed. There is a daily service of fast boats from English ports to Dieppe, the service being so good that Londoners frequently pass the week end at Dieppe; Americans, whether they land at Havre or Cherbourg, will only be a few miles from the course.

Description of the Grand Prix Course.

The circuit finally selected for the Grand Prix contest and the Sporting Commission Cup, to be run during the first week in July, consists of a triangular set of roads resembling closely in general appearance the Sarthe circuit of last year. Dieppe, a watering place of about 22,000 inhabitants, is the only important town on the course, and will doubtless act as general headquarters for the race officials and the various teams. Londinières hangs to another end of the triangular course, and Eu keeps guard over the northern point of the circuit. Londinières is the point nearest to Paris, being 105 miles northwest of the capital. The course is practically an equilateral triangle, the distances being Dieppe to Londinières 14 miles; Londinières to Eu 16 miles; Eu to Dieppe 17 miles. This gives a total of forty-seven or forty-eight miles; the exact distance has not yet been determined. As it is intended to run the race over a five hundred miles course, ten or eleven rounds will have to be made. With at least thirty-four cars, passages before the grandstand will be numerous, and there will be none of the waiting for cars to arrive, which has characterized recent French contests on long circuits. This change of policy is due to the desire of the French club to make the race more of a spectacular event, and a more profitable one financially. It is only because America proved that a short course was not dangerous for the passing and repassing of machines that France has decided to have a circuit of about the length of the Vanderbilt course. Starting from Londinières, the southern point of the course, and running up northwards towards Eu, a six per cent. grade about a mile and a half long, with two or three sharp turns, has to be climbed. The road is excellent, and at sixty-five miles an hour there is no jolting. There are several long, straight lines, then winding portions of just sufficient difficulty to keep the drivers alive to the business. Here and there a little hamlet of no importance, varied landscape, but always that beauty for which Normandy is famous the world over. The width is generally satisfactory; at various spots, the grassy side banks have been allowed to encroach upon the roadway, reducing the width to fifteen feet, but it will not be difficult to gain space where needed. The course passes right through the village of Eu, entering by a very wide road; there is a turn to the left in the central market place of the village, and a short, steep hill to climb. From Eu to Dieppe the course runs almost parallel to the seashore. The villages of Criel and Tocqueville are passed without any difficulty, then commences one of the finest racing courses to be found in France. Straight stretches, a few easy turns, ups and downs, and the Dieppe turn is reached.

It is probably on this leg of the course that the grandstands will be erected. Although known as the Dieppe turn, the town is actually a couple of miles away, a few houses stand at the corner, but the turn will be made without difficulty. The third leg of the course, from Dieppe to Londinières, is the weak portion of the circuit. The first few miles are moderate, and the villages of Ancourt and Bellengreville can be run through without difficulty. Envermeu straggles out on each side of the road for about three-quarters of a mile, and contains a sharp turn, which is likely to give some difficulty at high speed. The village is no sooner left behind than another difficulty presents itself. From Envermeu to Londinières an insignificant local railway runs alongside the course, and cuts down the width considerably. The railroad is mounted on an embankment varying in height from twenty inches to nine feet, thus forming a solid wall. A neck and neck race at this point is likely to be an emotional affair for both drivers and public. Arriving at Londinières the turn for the next leg of the course is exactly opposite the small railway station. Of course, on the day of the race the wheezy little engine will not pull its half dozen carriages and baggage wagon along at fifteen miles an hour. The contrast would be ludicrous. Everywhere the road surface is excellent. Envermeu will be as strongly barricaded as if it were to withstand a siege, and the thirty-four will be able to rush through without any fear of injuring the inhabitants or lessening the number of roosters. The turn in the village of Eu is on a very open place, and when strongly boarded round will be perfectly safe and possibly the most interesting spot on the course. As to the wall formed by the railway, there is nothing to be done; drivers knowing the difficulty will have to exercise a little caution. There were many more dangerous spots on the Auvergne course, which produced no accidents.

Some Good Features of the Circuit.

Advantages of the course are many. It is only three hours' railway journey from Paris; accommodation for big crowds can be obtained at Dieppe and the smaller seacoast resorts, the roads are of good average width, excellent surface, and well kept. Its proximity to the sea assures a mild temperature and will bring together many spectators willing to go to the seaside to see a race that would not interest them if it were run at some distant inland district.

It is probable that the race will be run left-handed, with the starting point on the seashore leg near to Dieppe. Grandstands and fuel stations will be erected here, the work of filling tanks, changing tires, etc., being in full view of the spectators. As is generally well known, there is no weight limit this year. The racers will be given half their fuel at the commencement of the contest, and will take up the remainder as they desire.

What Influenced the A. C. F. in Its Selection.

The Automobile Club committee from the outset has been the more favorable to the Seine Inferieure proposition on account of that district being "nearer England." Ah, that famous *entente cordiale* influenced many actions and considerations. To be near "our dear old England" is a pet proposition. With the race located in the Seine Inferieure, which partly borders the Channel, the chances are good for "English trade." Many Englishmen will cross over to see the contest, and, moreover, many Englishmen, during the summer, pass their vacations at French resorts all along the coast. Optimists even say that if the race is run in this part of France, King Edward will surely be "among those present," because of the convenience in arriving on the scene. It is argued that if the contest were held in the Eure, perhaps a hundred miles further from England, the King would hesitate about coming. There may be something in this line of argument, considering the fact that the King always travels third-class in an emigrant train and hesitates before extending his voyage.

CHRISTIE RACER FOR THE GRAND PRIX

AMERICA'S representative in the struggle between France, England, Germany, Belgium, Italy and the United States for the Grand Prix will be a front-drive Christie, now under construction in New York. The racer is an entirely new machine, differing in many respects from the ill-fated flyer of the Vanderbilt test. Frame is of channel section pressed steel, with rounded rear. Wheelbase is 100 inches, track 53 inches. The total weight of the machine is estimated at 1,780 pounds, this being in all probability the lowest weight of any car engaged in the Grand Prix. A large circular nickel steel crankcase is carried across the fore end of the chassis and assembles the whole of the motive power. The engine will have four separate steel cylinders bolted down to the crankcase, their dimensions being 7 1-4 inches bore by 7 1-4 inches stroke. They form two pairs, the second pair being slightly behind the first pair. A two-throw crankshaft is employed, with hollow steel connecting rods. Babbitt bearings are employed for the crankshaft. All valves are in the head, operated by rocker arms. Two speeds and reverse are provided, with direct drive on the high through double universal joint. Ignition will be by battery and coil. The engine is water-cooled, a very fine tubular radiator being employed. The engine is very compactly placed over the front axle and occupies but a small part of the length of the chassis. The radiator tubes running from one side of the frame to the other occupy all the room

between the engine and the dashboard. Water circulation is assured by a gear-driven pump. Lubrication is by a Pederson pressure feed oiler. The clutch is of inverted cone type covered with woven camel's hair. Semi-elliptic springs are used in the rear, with coil springs and a large rubber buffer in front. Expanding and contracting brakes are fitted to the rear wheels. The gasoline tank is carried behind the seats in a special cradle with metal against wood. It can be completely lifted out of its frame for examination or verification before or after the race. The capacity of the tank is twenty-seven gallons. As the total allowance of gasoline is about fifty-three gallons, it is intended only to stop once during the race for replenishing the supply. The gasoline is fed under pressure to the engine. The size of the wheels and the make of tires have not yet been decided upon. Christie patent rims, however, will be employed. The spokes will be of hollow steel and will be ten in number compared with twelve on last year's racer.

In the official engagement Walter Christie is entered as driver of the machine. We are informed, however, that the machine will probably be in the hands of Louis Strang, who acted as Christie's mechanic in the Vanderbilt contest. Walter Christie and his party will leave for France in time to thoroughly try out the machine on the course, and after the race will tour through Europe on a front-drive semi-racing machine.

SIX NATIONS AND THIRTY-FOUR CARS FOR GRAND PRIX

PARIS, Feb. 4.—Secretary Sautin, of the Commission Sportive, had closed down his desk and was preparing to leave the club rooms when an agreeable inrush of business detained him. The list of entries for the Grand Prix had been made up with a total of 29, and, owing to the early closing of the American mail, had been dispatched as final, both officials and pressmen being certain that no more would be received.

Thirty minutes before the official closing time a cable was received from New York. To the surprise of all it was found to contain the engagement of a Christie racer in the Grand Prix. Close on its heels came a registered letter with a check for \$1,000 as entrance fee for the Italian car Aquila Italiana. The two names were added to the list amid many expressions of satisfaction. "We shall have no more," remarked sober minded Secretary Sautin as he glanced up at the clock which registered 15 minutes to six. Just then the door opened and in walked M. Desjoyaux, the Paris manager of Mercedes interests, with 15,000 francs of blue bank notes in his hand. Three Mercedes were engaged. Business was not over, for behind the German agent were a couple of tire manufacturers with their modest contribution. It was a *coup de theatre* not usually seen at the A. C. F., and when the books had been closed and the money put under lock and key, it was not surprising that there were two or three joyous groups over an aperitif in a nearby café. To the list published last week in THE AUTOMOBILE should now be added the following:

- 30 Aquila Italiana (——).
- 31 Mercedes (Jenatzy).
- 32 Mercedes (Werner).
- 33 Mercedes (Willy Poege or Burton).
- 34 Christie (Louis Strang or Walter Christie).

In last year's Grand Prix there were 32 machines, representing three nations. This year there are 34 machines and six nations. France has the lion's share with 23 entries, her united competitors only numbering eleven. Now that Mercedes has come into line it is confidently declared in Paris that Fiat and

Itala will participate in the Grand Prix. Since the abolition of the weight limit and the imposing of a limited fuel supply, Germany and Italy have shown little enthusiasm for the French race. The idea seems to have prevailed that the French had discovered a new and more efficient fuel, which they would use to rout their rivals. The danger was more fancied than real, at least so declare the French officials, but the Germans and Italians readily believed what they suspected to be true. Germany has broken the ice, and every official on the Sporting Commission is rubbing his hands with joy at the prospect of three Fiat and three Itala paying double fees and carrying the total list of entries to the record figure of forty. The rules of the race allow late entries to be received at double fees until three weeks before the day fixed for the race. There is, therefore, no immediate hurry.

It will be noted that changes have been made in the composition of the Mercedes team. Jenatzy remains at his post, and is joined by Werner and Willy Poege or Burton, the Britisher. Werner is now in the employ of the German Emperor, and has charge of His Majesty's magnificent selection of automobiles. For a number of years he was the favorite driver of the late Clarence Gray Dinsmore.

Apart from engagements of cars three entries have been received for the tire contest held as an auxiliary of the Grand Prix. They are Falconnet-Perrodeaud, Hutchinson and Boland, all firms of secondary importance. Continental, Dunlop, Michelin, Engelbert and Samson have reserved tire stations on the course, but are not taking part in the competition. Since the beginning of the year a total of \$36,200 has passed into the hands of the A. C. F. officials in connection with the Grand Prix. Thirty-four thousand dollars came from entrance fees for the machines, \$1,200 for the tire competition, and \$1,000 for stations on the course. If the six Italian machines engage at double fees, as is expected, the total income from entries will reach \$48,200. The \$1,000 entrance fee gives the right to a repair station on the course, but any other firms not taking part in the contest, but having some direct interest, may engage stands at \$200 each.

ESSENTIAL ELEMENTS OF ELECTRIC IGNITION

By CHARLES B. HAYWARD.

THERE is probably nothing connected with the operation of the internal combustion motor as represented by the types, in which it is at present used in such large numbers in automobiles and motor boats, that puzzles the user to the same extent as does the ignition. It is not alone one of the most profound of mysteries to the beginner when entering upon his novitiate, but it remains so longer than anything else about the motor. Doubtless the popular and widespread impression regarding the mysterious nature of electricity as a force that prevails is largely responsible for this, while the fact that such a belief is fostered rather than corrected, by the awesome regard in which the average autoist holds the subject, may probably be held accountable for the slow progress made. But a far more potent factor in retarding the thorough education of the everyday driver in this subject, is to be found in the fact that he approaches it from the wrong end; he is confronted by an application of electricity and is compelled to master its ins and outs wholly through observation and practice, the greater part of which must necessarily be of the "hit and miss" variety. Not having any foundation of knowledge or experience upon which to fall back, he must grope blindly for trouble whenever called upon to remedy it. Despite this, however, the majority of autoists come to have a fair knowledge of the ignition system as a whole, in the course of time, but as a consequence of this manner of acquiring their education, they never learn the fundamental principles underlying the subject, a knowledge of which is essential to its thorough understanding.

FIG. 1.—Conventional symbols generally employed in electric wiring diagrams to represent the various forms of apparatus used in the circuit. As explained in the text, these are battery, generator, polarity indicators, switch in open and closed positions, and an induction coil.

Learning the Rudiments an Absolute Necessity.

Any system of education which started the beginner at the most advanced stage of the curriculum and compelled him to master it without ever being enlightened in its groundwork, would naturally be considered absurd, yet this is the way the average autoist gains his knowledge of ignition systems generally, and the subject of electricity as applied to them. In the present article it is the purpose to outline the rudiments of the matter before passing on to a consideration of the various systems of ignition now in vogue, together with a statement of their advantages and disadvantages as revealed by extended practice, as well as the trend of current practice as shown by changes that have taken place during the past few years. As a means of doing this in a comprehensive manner, it has been found necessary to divide the subject into several parts, in each of which a study of the various essentials of the electrical method of ignition will be taken up, as closely as possible, in the order of their importance. In treating any such subject as this, it is naturally impossible to give equal heed to the status of every autoist or every group of autoists, where the matter of electrical education is concerned; many are well advanced and feel so far above anything that savors of the elementary, as to pass it by disdainfully; others not so far along find descriptions couched wholly in technical terms and without further explanation, beyond their comprehension, while there is a very large class to whom even the rudiments of the subject are as Sanscrit, and it is to this group that the first chapter of this article, at least, will appeal. Only such terms as are essential to a proper comprehension of the

subject, and which even the novice feels the necessity of being able to use understandingly, will be employed.

Characteristics of Electric Currents.

Naturally the first thing the beginner wishes to learn is, What is electricity? He is not alone in this desire, for the most erudite of scientists have been attempting to solve the problem to their own satisfaction for many years. While knowledge and skill in the generation and handling of electric currents have reached

FIG. 2.—Symbols continued; ground connection, multiple way switch, single, double and quad timer.

an advanced stage, particularly within the past decade, there has been no material progress made in the purely academic side of the subject, so this first and most natural question must go unanswered. As may be surmised, the exact nature of this mysterious force is not essential to an understanding of its use in this connection. Electricity is assumed to flow, and this is also a moot question, as just how it travels, whether in a wire or along its surface, is not known, but for present purposes, the assumption may be taken as correct. From early days, writers on the subject have compared the action of an electric current to that of water flowing in a pipe, and no better simile to illustrate some of its most important characteristics has ever been devised, as both are analogous in many respects.

Thus, water flowing in a pipe, must be under pressure, and the same is true of an electric current; it must have volume, and this is also true of electricity. Both meet with a certain amount of resistance to their travel, and in both cases the result of their action is similar; in other words, pressure times volume, less resistance, will give the amount of water of which a certain size of pipe is capable of delivering, and these factors are equally available to calculate the amount of *current* passing over a given wire, except that distinctive terms are naturally given these factors to distinguish them in the case of the latter. For instance, pressure is calculated in terms of voltage, potential or electromotive force, usually written "e. m. f.," these three being synonymous. The volt, named after Volta, the Italian scientist in honor of his researches in this field, representing the unit of pressure, is the electrical equivalent of pounds per square inch in the case of water flowing in a pipe. To indicate volume, the term Amperes is employed, its derivation being similar to that of

FIG. 3.—Theoretical wiring circuit for single cylinder motor; without timer.

volt, Ampere having been a noted French investigator. But in any consideration of volume, the time element must enter, as gallons per hour in the simile mentioned. This has its equivalent in ampere-hours—a term most commonly employed in speaking of the storage battery or accumulator, and indicating its capacity to perform work. An ampere-hour represents one ampere of current passing for one hour. In the case of the third element, resistance, this is denominated by the term Ohms, of a similar origin to the other two, and representing the unit of

FIG. 4.—Two ways of opening a circuit; with the switch or by an accidental break in the wire; the latter falling free.

resistance to the passage of a current. This and the term Watts, which is the product of voltage multiplied by current, and represents power, are something with which the autoist who does not carry his study of electricity beyond the point required to master present-day ignition systems and their operation, will have little to do and need not burden his mind with needlessly, except insofar as they have a direct bearing on the other elements.

Numerous Popular Fallacies Extant.

Before proceeding any further with this part of the discussion, it will doubtless be found profitable to digress momentarily to explain some of the most erroneous impressions that exist in the popular mind with regard to the nature and action of an electrical current. Probably the most common of these is that regarding the condition of an object, such as a wire, through which a current is passing at the moment—what is known in every-day parlance as a “live” wire. This is generally said to be “charged” by those knowing no different, and contact with anything “charged” is universally considered to result injuriously, if not fatally, to the person touching such a wire. “Live” is both an apt and expressive term to apply to a wire carrying a current, from the popular point of view, but such a wire can never be said to be “charged” in any sense of the word. In other words, it does not store up electricity and give it forth suddenly when contact is made with it, as does a storage battery when short-circuited on itself, or a condenser, or Leyden jar, the latter being but different forms of the same thing; but of these, more later. What does actually happen, is that when a person comes in contact with such a “live” wire, as by placing his hand or other part of his body on it, if he be standing on a good conductor, the latter forms a path for the return of the current to its source, and in consequence, it passes through him. That is, his body has served to bridge a gap and form a short-circuit—the result is popularly termed a shock, but the manner in which it may be received involves a proper understanding of the meaning of the terms, circuit, short-circuit, ground, earth connection and leak, all of which are constantly employed with reference to ignition troubles.

If it be desired that water flow out of one part of a tank and in at another, as is the case in the radiator of the cooling system of a car, it is necessary that there should be a conductor for the water traveling in each direction; the same thing is true of an electric current, and when there is no interruption at any point of either conductor, there is said to be a circuit. Causing such an interruption as by opening a switch, converts it into an “open” circuit; no current passes. Breaking a wire and permitting the broken end to come in contact with something that provides a return path for the current, or allowing the wire to chafe against a moving part of the motor until the insulation is worn off, thus accomplishing the same end, creates a short-circuit. The current finds a new return path to its source, thus completing the circuit short of the point the current is intended to reach, as the spark-plug. Electricity always follows the path of least resistance, so that in order to have a short-circuit, the new path opened by the broken or chafed wire must be of less resistance than the old. If its resistance be very much higher, as in the case of the chafed wire rubbing against some insulating material, nothing happens; as this resistance decreases there will be more or less leakage, but there will be no short-circuit as long as it is appreciably higher than that of the original circuit. If, in the case of the broken wire, this does not strike against anything that forms a return path for the current, the circuit becomes an open

one just as if the switch had been moved intentionally. This is generally termed a short-circuit by the average autoist, but as will be evident there is no circuit at all, or the current would flow, the term open-circuit being somewhat of a misnomer. Other causes of opening the circuit are found in loose connections, permitting the wires to drop, or similar accidents that interpose a gap in the circuit, stopping the flow of the current.

Properties of Various Materials.

In order to gain a fuller understanding of this apparently perplexing matter, the nature of various substances with regard to the electric current must be taken into account. For present purposes it is only necessary to divide them into two classes, that of conductors and non-conductors or insulators, the only element complicating the problem being found in the fact that under certain conditions the same material changes its nature. For commercial purposes the best conductor is copper, and the best insulators are porcelain, glass, fiber, hard rubber, paraffine wax, oil, silk, cotton, wood and the like. All metals, metallic substances and carbons are conductors, and most materials not of this nature are non-conductors, but under the influence of heat some of them lose this property, such as wood and cotton when carbonized by charring, and when wet with water or any alkaline or acid solution, the latter will form a path for the current across any of them. This brings up the subject of “ground” or “earth returns,” the latter being an Anglicized expression. As originally employed all telegraph and telephone circuits were “grounded;” that is, the current was sent from the sending to the receiving station over a wire and permitted to return to its source through the earth. Hence, every circuit not employing an independent return wire has come to be known as grounded, and this represents practically universal practise in the case of automobile wiring, whether the low or high-tension system be employed, and regardless of the source of current.

To give a few concrete examples of this, it may be recalled that it was customary on early cars to make this ground connection from the battery on the nearest part of the chassis that happened to be convenient, and the same was true of the secondary circuit or wiring to the spark plugs themselves, though in

FIG. 5.—Theoretical illustration of a short-circuit; broken wire has become grounded, cutting out the coil.

this case the extremely high potential of the current and its ability to pass over or around obstacles did not render this a matter of the same importance. In the case of the battery, however, with its potential of but six or eight volts at the most, it is different; extra resistance present in the circuit prevents the flow of current exactly the same as restricting the outlet of a pipe through which water is issuing, would lessen the volume delivered. As a result sufficient current does not reach the coil to give satisfactory service, and either the battery or the coil is held responsible, whereas there is really nothing at fault but the poor ground connection. Oil, as already mentioned, is a good insulator, and as a properly lubricated bearing is always surrounded by a film of oil, it will be evident that a

FIG. 6.—Illustration of manner of grounding one side of each circuit on single-cylinder motor; timer omitted.

ground connection which includes such a bearing as the crankshaft in its path is not apt to be of the highest efficiency. While all metals are good conductors, where two pieces are joined, as at the battery or generator, the surfaces must be clean and

FIG. 7.—Illustrating numerous combinations possible with batteries.

held in firm contact in order not to create extra resistance in the circuit and cause the same trouble as a poorly placed ground connection—that of decreasing the amount of current.

Commoner Symbols and Connections Explained.

Although it is customary with the majority of makers of ignition apparatus to show the various essentials in a circuit such as coils, timers and the like in perspective so as to be readily recognizable by the uninitiated, this is not always the case, and it is well besides for the autoist to be able to recognize them when shown diagrammatically. For this purpose a number of symbols are employed. They are shown in the accompanying sketch and lettered so as to be readily distinguishable. A being the conventional symbol for a battery, each light and heavy line representing a cell so that the drawing is the equivalent of a battery of four cells. Sign B represents any mechanical source of current, such as a dynamo or magneto; in power wiring diagrams, the letter "G" or "M" is inserted in the circle, signifying generator and motor, respectively—in this connection it will be found convenient to have them represent generator, meaning a small direct-current dynamo, and magneto. The next signs are the conventional plus and minus symbols and are employed to designate the polarity of the current or direction in which it is flowing, the plus or positive terminal usually being understood as the point at which the current issues from its source, and the minus or negative that through which it returns, completing the circuit. These signs are of particular importance in connection with the use of storage batteries which must always be recharged in the same direction. The sign D is a conventional representation of a switch shown both in the closed and open positions, reading from left to right, while the next sign, E, represents an induction coil, the thick lines being the heavy or primary winding of the coil and the fine lines, the secondary winding. In the second line of symbols, F represents a ground connection already explained, G is what is known as a three-way switch, the only difference between this and the symbol already shown being the greater number of contact points which may be multiplied indefinitely according to the number of circuits the switch is intended to control; the use of this form of switch is made clear further along. In order that the spark may occur in the cylinder at a certain time, it is customary to insert what is known as a contact maker in the circuit; as used on single-cylinder motors and in magnetos, this is represented by the sign H; in multi-cylinder engines a more complicated form of timer is employed, this being represented in the case of two and four-

cylinder engines by the signs I and J, the only difference lying in the number of contacts, from each of which a wire is led to the spark plugs. In the case of a distributor, which may best be described as a sort of duplicate timer, half of which times the primary or battery current and the other half of which distributes the secondary or high-tension current to the plugs synchronously with the working of the timer, the same sign as J will be employed, except that eight instead of four connections are shown.

Wiring of Simple Forms of Circuits.

The signification of the term circuit as well as the various ways in which it is employed have already been explained at some length. In the series of sketches appended, an attempt has been made to show the meaning of these terms diagrammatically. For instance, Fig. 1 illustrates the wiring of an ordinary single-cylinder motor, the timer being omitted; in this sketch both the battery circuit to the coil and the high-tension circuit to the plug are closed. With the switch closed as shown there would be a continuous stream of sparks at the plug as long as the battery lasted. In Fig. 2 the switch has been opened and one of the wires broken, illustrating two means of making an open circuit; even though the switch were closed, no spark would occur at the plug owing to the break in the wire. The switch is shown closed in Fig. 3, but the broken end of the wire is presumed to have fallen on something providing a return path for the current. This is a short-circuit, and the path that the current would take in returning to the battery is indicated by the dotted line. From this it will be seen that there is a complete circuit so far as the battery is concerned, but the current does no useful work. These sketches have been prepared merely to illustrate the terms in question and do not represent actual methods of wiring. A closer approach to the latter is shown in Fig. 4; the timer, if shown, would be placed in the wire leading from the switch to the coil. This shows that one side of the battery, the positive in this case, has been grounded; the same thing has been done with one side of the primary winding of the coil. The current finds its way back to its source through the metal parts constituting the ground and thus the return wire shown in the previous sketches is done away with. One side of the secondary winding of the coil is also grounded and the same is done with the plug, the ground connection in the case of the latter consisting of the contact it makes with the engine by being screwed into the cylinder head, and is not a special wire as indicated by the drawing. This simplifies the wiring greatly by making but one wire necessary for each plug. In at least one instance extant a ground connection is not depended upon, two wires being used, but this is only carried out on one make of single-cylinder cars.

Various Forms of Connections.

The foregoing has dealt entirely with the varying character that may be given a circuit, whether by accident or design; but there are, in addition, other ways in which they may be changed. The word battery always represents a combination comprised of

FIG. 8.—Diagrammatic representation of methods of connecting batteries usually employed.

several units, known as cells, which, in turn, are composed of elements, regardless of what type it may happen to be, such as primary or secondary, dry or wet, a secondary being more commonly known as an accumulator or storage battery. There is no necessity in the present connection to go into the matter of the chemical actions and reactions which produce the current

in a battery, but the distinction between a battery and a cell should be borne in mind, as well as the fact that each cell has a positive and a negative terminal. This is also true of every source of current. When dry cells are employed it is customary to use two sets, and the simpler forms of wiring will be explained with this in mind. When all the elements of the same nature are connected together, the cells are said to be in multiple and in this form the combined output in amperes is the sum of the individual capacities of the cells, while the voltage is that of but one cell. Referring to K, this represents six dry cells in multiple, and if it be assumed that the voltage of each cell is 1.5 and the amperage 10, the combined output would be 60 amperes at 1.5 volts. L represents the same six cells connected in series, alternate terminals being connected in every case, this giving the combined voltage of six cells with the amperage of one, which with the above figures would give a current of 10 amperes at 9 volts. The next diagram M shows the two sets of dry cells generally employed connected in a combination of these two forms of wiring known as series-multiple or series-parallel, which mean the same thing; that is, each set of six is connected in series so far as its cells are connected and each set is taken as a unit and connected in multiple, the combined output then being a current of 20 amperes at 9 volts; the last of these figures, N, represents both sets in series, giving an output of 10 amperes at 18 volts. As the voltage of a dry cell drops rapidly in use, especially when old, this is sometimes resorted to with a battery that is practically exhausted and will sometimes suffice to run the motor for a few hours longer.

The next series of illustrations is practically a repetition of those just described, using the conventional symbols, although there is shown in addition the method of wiring usually employed to effect the different combinations referred to by means of a multiple point switch. O represents the two sets of cells in series as in N, while P shows them in series-multiple as in M. Cells are never used for ignition purposes in simple multiples, as shown at K, owing to the low voltage. At Q is shown the wiring necessary to use either of two sets of dry cells or both in series, and at R the number of combinations is increased by the use of a four-way switch permitting either set to be used independently, both sets in series-multiple or both sets in series, the connections necessary for series use being indicated by the dotted lines in both Q and R. Sources of current will be considered in the next part of the present article.

LUBRICANTS FOR ALLOY BEARINGS.

It has been stated that any kind of grease or oil may be used with the Babbitt's mixture already given, but when this is softened down with lead, or with any alloy having zinc and lead in its composition, care should be exercised in the selection of the oil used to lubricate it, as such selection forms a considerable factor in the life of the bearing, says A. A. Suggate in a treatise on bearing alloys. It is often a question of some importance in designing the commoner class of machinery—say, agricultural or coal elevating, for instance—whether to put in high-price bearings, for which any kind of cheap lubricant may be used, or bearings at a less cost, yet, to be equally as efficient in the matter of wearing as long, would necessitate the use of a lubricant costing twice to three times as much as the lubricant necessary in the higher-price bearings.

MONEL IS SAID TO RIVAL NICKEL.

A new metal, called monel, is being produced at the works of the Canadian Copper Company, at Sudbury. It is cheaper than nickel, and it is claimed that it possesses all the qualities of the former. Monel is a compound of copper, nickel, iron, and one or two other minerals which are found in the district, and its importance lies in the fact that it is much cheaper than nickel, it is less liable to rust, and will serve all the purposes for which nickel is at present used. The new alloy is said to be of equal ductile strength with nickel, and to possess all its other essential qualities, which should give it a high value.

AMERICA LEADS IN NUMERICAL VALUE.

In numerical value the United States is at the head of the automobile producing nations of the world. Starting last, with but 314 cars in 1902, four years later, in 1906, the numbers had reached the formidable total of 60,000. In 1898 Germany had a slight lead on England, but soon lost it, and for the last nine years has followed in the wake of her industrial rival. Belgium did not figure with any prominence in the automobile industry until the year 1900; her increase was at first slow, but during the last two years she has made enormous progress. Italy was a still later arrival, and a very modest one at the outset. In 1901 she produced 300 cars; the following year the number was only very slightly increased, but for the last four years her numerical growth has only been eclipsed by that of the United States. Italy, however, has always produced high grade cars, and her real position in the automobile world is not revealed by figures on numerical output. The following table, compiled by the French authority, *La Finance Automobile*, shows the number of automobiles constructed in France, England, Germany, Belgium, Italy, and the United States from 1898 to 1906.

Year.	France.	England.	Germany.	Belgium.	Italy.	U. S. A.
1898.....	1,631	682	894
1899.....	4,914	1,143	1,478
1900.....	10,039	2,481	2,312	400
1901.....	16,486	4,112	3,209	600	300	...
1902.....	23,711	6,253	4,738	1,700	350	314
1903.....	30,204	9,437	6,904	2,839	1,308	2,722
1904.....	37,322	14,170	11,370	5,026	3,080	11,374
1905.....	47,302	20,848	15,682	7,927	8,870	23,877
1906.....	55,000	28,000	21,000	12,000	19,000	60,000

SPRING WHEELS FEASIBLE ON PAPER.

FROM THE AMERICAN MACHINIST.

An indiarubber tire becomes very hot when at work. The kneading to which it is subjected produces internal friction within the body of the material, and the tire will frequently become hot to the point of bubbling or smoking. On paper it is a very easy matter to design a steel wheel with internal springs that will work with perfect satisfaction—again on paper. This problem of the spring wheel is one of many years' standing with the makers of heavy traction engines. Many spring wheels have been invented, numbers of them have been tried. All, or nearly all, have failed. A steel spring has only a limited life; it will only bear, before breaking, a certain limited number of flexions. Some wheels, apparently of sound mechanical design, fail from dirt and grit. A spring composed of a block of indiarubber inclosed in a supporting metal cylinder might be expected to endure. But indiarubber has its limits even when thus supported. The whole problem, in fact, bristles with difficulties. It is urged that all these difficulties would be eliminated by the use of a perfect road surface, on which truly circular wheels of steel would run without shock.

IMMENSITY OF RECENT BERLIN SHOW.

Consul-General A. W. Thackara, reporting on the recent international automobile exhibition at Berlin, states that there were 980 distinct exhibits shown by 371 firms, companies and individual manufacturers, as compared with 320 exhibits and 298 firms in the exposition of February, 1905. Of the exhibitors 338 were German, 17 French, 5 Italian, 4 English, 3 American, 2 Belgian and 2 Swiss. This classification designates only the nationality of the direct exhibitors and does not explain the large number of exhibits, such as machinery, automobile parts and accessories made in other countries and exhibited by German firms acting as agents for the sale of such products in Germany. For example, Schuchardt & Schutte, of Berlin, exhibited a fine collection of American lathes, drill presses, milling machines, etc., for making special parts of automobiles. The machines came from Cleveland, Cincinnati, Waynesboro, Newark, etc., and, being largely automatic and exhibited in operation, formed a display which attracted absorbing interest.

TO ATTAIN ACCESSIBILITY AND CLEANLINESS*

By F. L. MARTINEAU.

IN tackling a paper on this subject I have endeavored to put before you the ideal to be aimed at, and to indicate how this ideal may, in some degree, be attained. During the preparation of the paper, certain points cropped up which more or less bear on the subject, such as the number of cylinders to be used, but these I have eliminated entirely from the subject matter of the paper. I have tried to consider each item from the standpoint both of the vertical and horizontal engined car.

As regards the two points in the title "Accessibility and Cleanliness," they are so intimately connected the one with the other that I have had to consider them together.

To begin with the ideal of cleanliness, it is, I think, that the whole exterior of the car should be smooth and easy to clean; that no mud or dust should be thrown by the wheels on to any part of the mechanism, or the carriage body; that all working parts should be thoroughly protected from grit; and that all oil drippings should be caught in a detachable receptacle.

Many Things to Be Considered.

The great question on which the whole problem of accessibility hinges is this: Why is it needful to be able to get at any parts of the mechanism? If it were not, the matter of cleanliness would be an easy one, as one could seal the whole mechanism up like sardines in oil and let it look after itself and yet always keep the exterior spick and span. Under these circumstances it would necessitate the designer so proportioning the various parts of the car that nothing ever wanted adjusting or replacing, and the end of the car would be like the one-horse shay, which collapsed into nothingness after its period of life was fulfilled. Unfortunately, it is impossible so to foresee the very varied conditions of working and the attention, or rather, the lack of it, bestowed upon our productions that they will wear out evenly, nor is it possible to provide against accidental breakages.

This being so, it may be necessary to remove or adjust any part, and so to obtain the ideal of accessibility, we may lay it down as an axiom "that we ought to be able to remove any one part without disturbing any other." This ideal, like all ideals, is practically impossible of attainment; to approach within reasonable distance of it would necessitate every part being exposed and in view, which would prevent obtaining efficient means of protection. The best we can do, therefore, is to study the easy removal of those parts liable to wear and use as a foundation on which to build up these parts all pieces not so liable.

The very first thing to consider, therefore, is the general scheme of the whole car, and in this the body is the item of greatest importance. What is the use of having an engine nicely housed in a bonnet in front, easily opened and inspected, if the gear box and other vital parts are made inaccessible by the carriage body, as on a car I found stranded by the roadside the other day. In this one of the gear wheels was pushed into mesh by a fork which, having got strained, refused to work; it was almost impossible to do anything to it, as the carriage body was in the way of the cover of the gear box. The body, undoubtedly, should be easily raised or moved so that all running gear can be easily and efficiently inspected.

Placing of Body a Strong Factor.

Now, the position of the body depends principally upon the permissible wheel base. What is the maximum wheel base which is easily handled and utilized in all districts? I have come to the conclusion that nine feet is the maximum, and I derive this figure from experience of cars of various wheelbase on the roads around my home in Devonshire. Having the size of a suitable

body, we can ascertain the available space for engine, etc. Take a landaulette body, the type most in vogue. This to be really comfortable must have a total length from dash to back of 108 inches, which is the same as the wheel base.

As it should not project behind the center of the rear wheels to give absolute comfort to the passengers on the back seats, the dash will come level with the center of the front wheels. This does not give enough room for an engine of the accepted vertical type; it is thus imperative to adopt some other position for the engine or curtail the seating accommodation. If the engine is a vertical one it can be placed in a bonnet between the driver and passenger in front, or it can be arranged under the driver's seat. Another way out of the difficulty is to utilize a horizontal engine.

Other Parts Besides Engine Need Attention.

To render every part accessible the body can be made to rise on hinges at the back, which done, the whole of the running gear, and not merely the engine, is at hand and in view. Should not the gear-box, etc., be cleaned and inspected just as often as the engine? To inspect the engine and gear-box separately the front and back floor boards can be removed, the former for the engine and the latter for the gear. As to the removal of the floor boards for inspection purposes, if these are made to lift out there is a greater liability of the mud and dust collected on them being emptied on to the parts below. I am, therefore, making them to slide out of the way under the seats and yet arranging them so that they lift up with the body.

As a general practice, it may be laid down that the whole of the chassis should be erected, and every part should be accessible from above. The true meaning of this is that with a car so designed a pit is no longer a necessity, and also that the most perfect cleanliness can be arranged for, as the undershield can be made absolutely continuous and permanent.

The number of sizes of nuts used in a car should be reduced to a minimum. I am now using only five sizes on the whole car, which means that the total number of spanners necessary to undo any nut is greatly reduced. To deal with any nut will require only three tubular box spanners.

Of the spanners which I have mentioned as necessary for my car, the jet spanner is the smallest, and this is now being made to fit all nuts on the ignition parts. All screws on the carburetor, etc., are also being made with hexagon heads to fit this spanner as well as a screwdriver slot.

The other method employed of locking nuts is the other point I mentioned.

An American Motor as a "Horrible Example."

An example of the indiscriminate use of nuts came before my notice some months ago in an engine which, originally of American design, was being brought up to English practice so as to be placed on the market here. The only way of describing it is by saying that it looked just as if a bucketful of odd sizes of bolts and nuts had been poured on to it, and that they had been fitted where they fell. To take any part off required about five spanners and a screwdriver. This state of affairs, I am pleased to say, has now been remedied.

In the consideration of the position of nuts and bolts it is general practice to arrange them through a boss; this in nine cases out of ten projects outside the case or whatever part it belongs to. It is also common to find gear cases and engine cases shaped so as to fit close to the gears inside. When a case is so arranged it may be very nice designing, but it always appears to me that if it were smoother and flatter outside, the bosses being arranged as much as possible inside, the weight would not be very much, if at all, increased; it would be much more easily

* Paper read at meeting, Institution Mechanical Engineers, St. James Park, London, January 16, 1907.

cleaned, and it would simplify the patternmaking, and in all probability cheapen the moulding, and, perhaps, make the holding of the piece in its jig for machining much easier. The most important point about having cases smooth outside is so that, in the event of anything requiring to be done inside, the outside may be made absolutely clean before it is dismantled. Under these circumstances, grit will not find its way into the interior when the parts are in the hand of the repairer.

Accessibility of Engine Details Paramount.

We now come to detail design, and will consider the engine first.

If this is of the vertical type, many difficulties exist which may not appear at first sight. To comply with our axiom it should be possible to withdraw a piston without disturbing any other part. To do this necessitates a very large hole in the side of the crank case, or else it must be done from underneath, which is generally very inconvenient. If it is arranged to be taken out at the side, to make it really convenient the engine must be fitted very high up in the frame—so high, in fact, that the fly-wheel and other parts will more or less interfere with the carriage body. Of course, if there is a hand hole in the crank case sufficiently large to take down the big end easily, it is possible to remove a piston by dismounting a cylinder. This method, however, is crude and unpractical in most engines by reason of the number of joints to be broken, and it does not at all fall in with the axiom with which we started. On a horizontal engine it is possible to make the whole of the top side of the crank case to come off without impairing its strength, and then the whole of the crank shaft, connecting-rods, and pistons are in view.

As to the cylinders themselves, there seems to be at the present time a great wave in favor of casting them all together. This may be good from a constructive point of view, but it is not so from the point of view of accessibility and repair. It has one advantage in its favor, and that is, it enables the whole of the valve stems and springs to be encased. The question is whether this is necessary. As long as we encase the engine in a nice bonnet and under shield, and then pump air laden with dust and mud through the radiator and over the engine it will be necessary. Should we not rather seal the engine up and pump the air from the radiator around and out at the back of the car? This would tend to keep the exterior of the engine cleaner, and allow of a large amount of casting at present fitted on the engines being dispensed with, and fitted instead as a casing for the grit-laden air to pass through. Reverting to the cylinders, in the whole of my experience I have never had to replace a cylinder because it was worn out; but still, I advocate casting them separate.

Cylinder and Manifold Removals Considered.

To my mind, a cylinder should be easily detached without removing even an inlet, water, or exhaust pipe, but only breaking the joints. The valves on most engines nowadays are easily removable, but it should not be necessary, in removing them, to have to take off the spring. This should be arranged to be supported whilst the valve is withdrawn and ground in. At the same time, a valve spring itself should be easily replaceable in case of breakage. Another part which is usually rather difficult to get at is the gudgeon pin. In most cases this is fixed by two taper-pointed screws. As these require very carefully locking with nuts, and are very close up to the side of the piston, they are practically only removable with special tools. At the same time, they have the disadvantage of causing the piston to become oval when hot, as the expansion of the piston and gudgeon pins are slightly at variance. To obviate this, as long ago as 1899 I fixed the gudgeon pin in the small end of the connecting-rod by a taper pin, driven through on the side away from the big end.

Positions of Ignition and Carburetion Details.

The ignition distributor or commutator should be arranged so as to be easily taken apart and cleaned. This I have managed by making the rotating center spindle and contact cam withdraw out of its bearing, leaving the whole interior free for cleaning; the

end of the spindle is driven by a dog clutch so that it can only be fitted in its right position. The camshaft should be made to come away sideways; when made to withdraw from one end it often necessitates the taking down of some other part. It is better to my mind if arranged so as to be inspected by simply taking off a cover.

The carbureter is a part of the anatomy of a petrol engine that has received an enormous amount of attention in the last few years, but I am sorry to see that the tendency has always been to add parts, and not to eliminate them. Some of the later types may or may not be more efficient than their predecessors, but they certainly are not more accessible. It is impossible in most of them to ascertain if the petrol stands at the correct height in the float-box, for the simple reason that the float valve has its gear on or is guided by the cover. Why should it not be made independent of the cover? Similar contrivances for other purposes have been in use for years, and are always made accessible, yet a carbureter, which depends on the accuracy of this adjustment, in a great measure is incapable of correct adjustment. The design which I now use has the float on one end of a lever, the other end of which presses on a horizontally arranged needle valve. In this way the needle valve and its seat can be withdrawn together by undoing the petrol pipe union, and the petrol level can be observed and checked with the top of the float-box off. The float, too, can be easily removed.

Necessity for Dust and Water-Proof Shields.

In many cases the exhaust pipes will be found on a car wrapped up with asbestos; instead, they should be carried out of the way. It is essential to have an under shield completely enclosing the engine; it should be quite tight-fitting, and if it is necessary to have a hand hole in it, the hole should be large enough to work through and a good three-eighths bead carried around it.

Before we finally leave the engine, there is one other part I must mention, and that is the adjustment usually fitted on the coil trembler. This, as a rule, is a screw with a milled head passing through a bridge piece, and a hexagon lock nut to fix it after adjustment. This nut nearly always requires a special thin spanner, as the space between the milled head and the bridge is not sufficient for one of ordinary thickness, and it has the further disadvantage that the locking of the nut by pulling the screw up into the threads disturbs the adjustment. A much more accessible way of doing this is by splitting the bridge vertically throughout its length, and fitting a screw through, coupling the two halves, and so clamping the adjusting screw.

Getting at Change Speed Gears and Drives.

We now come to the clutch and gear box. In the majority of cars at the show at Olympia these two parts seemed to have received the greatest amount of attention to make them individually accessible. Whether they were so collectively with the carriage body mounted seemed to be to a very large extent left to the tender mercies of the carriage builder. Given that the carriage body is not in the way, there is very little to note with regard to either of these parts, as they can be made so easily dismantled. We now come to the back axle, and the more I go into this the more there is to say. So many different types are in use, and each must be considered separately, that I think it better only to mention a few points to be considered. The chief features which have to be retained in view are these: Either wheel should be easily removable. The differential should be accessible. It should be possible to correct the adjustment of the drive, be it bevel, chain, or worm, and the brakes should be easily adjusted, and their adjustment should not require altering to remove a wheel. From the point of view of cleanliness, if chain drive is used, the chains should be encased if outside, or else the under shield should be so prolonged and shaped to protect them.

As regards the steering, this is usually arranged so that the various connecting-rods are outside the under shield, and the joint ends protected with leather covers. I prefer making all the connections inside as much as possible, and have designed the joints so that they are dust-proof.

LETTERS INTERESTING AND INSTRUCTIVE

Increasing an Engine's Horsepower.

Editor THE AUTOMOBILE:

[579.]—Will you inform me how I can get more power from a four-cylinder motor without increasing the size of it? The bore is 4 inches, and the stroke 4 1-2 inches, while the compression is very low. The motor can be run any length of time on any gear without overheating. It is my idea to lengthen the connecting rod slightly, with a view to securing more compression, as the motor is water-cooled. It seems to me that the change should be O. K., unless the valves would have to be changed, which would be impossible. Would you advise my making any changes, and if so what would you suggest?

H. T. G.

Waterbury, Conn.

If you are very sure that the compression is low, and are willing to take a small chance of rendering the motor more likely to overheat, an increase in the compression will increase the power. And if the water-cooling system is well designed there should be no very serious danger of overheating. Your idea of lengthening the connecting rods to secure the desired increase in compression does not particularly appeal to us, as it seems likely to involve you in other difficulties. It will, in the first place, cause the pistons to travel higher than they are designed to travel, with the result that they may overrun the counterbored ends to the wearing surfaces nowadays provided for in the design of practically all high-grade engines. Besides this, it may cause the connecting rods to strike the sides of the cylinder ends, if the clearance at these points is figured as close as is not infrequently the case. A much better plan would seem to be that of partially filling the combustion spaces by screwing plates against the insides of the cylinder heads. Sometimes such plates are attached to the pistons, but the objection to this is that they increase the weight of these rapidly-reciprocating parts. We hardly feel inclined to advise any very extensive changes, especially without knowing the make of the motor, so that we can have some idea of how good it is in its present condition, but a little experimenting in the way of filling up the combustion chamber in the manner suggested hardly can do any harm. If there is any possibility of the valves being too small—a not uncommon fault with many early engines—changes in other details are not likely to help matters materially. Sometimes, with an engine of definitely poor design, amplification of the inlet piping proportions, or a change in muffler or carbureter, will effect a very marked increase in power.

A Correspondent Takes an Exception.

Editor THE AUTOMOBILE:

[580.]—In reference to letter of Clarence T. Jones, published in your paper as number 543, I would like to say that I thoroughly agree with Mr. Jones, and consider that he has in his letter given a very excellent idea of battery consumption in connection with a timer and vibrator and, although I do not know him, I consider him a man who thinks. I will also say that the idea that you are giving by the answer to his letter is entirely wrong, and I base my statement on actual experiments performed. I am sure that you will be able to confirm Mr. Jones' statement as correct by reference to any reputable manufacturer of spark coils.

Chicago, Ill.

FREDERICK K. ARTHUR.
